# **The effects of nanoparticles on the physical properties of type I collagen**

A thesis presented in partial fulfilment of the requirements for  
the degree of

Master of Science  
in  
Chemistry

At Massey University, Palmerston North, New Zealand.

**Jiixin Lian**

2016

## **Acknowledgements**

I would like to thank everyone who gave me guidance and support throughout my master project. I would like to thank in particular:

My primary supervisor Prof. Bill Williams for his supervision and encouragement. There were so many times when I was stuck and frustrated but a conversation with him made me relax and had a clear idea about what to do next.

My co-supervisor Dr. Sujay Prabakar for his time for discussions and encouragement, and giving me the opportunity to undertake this project for my master.

Dr. Bradley Mansel for his help and assistance in conducting some experiments, developing experimental protocols and data analysis.

Dr. Allan Raudsepp for his training on the rheometers.

Dr. Meekyung Ahn for her training on collagen extraction and characterization with SDS-PAGE, and her encouragements during my study.

Niki Murray for conducting the confocal microscopy imaging.

Dr. Bridget Ingham for the training and discussions on the synchrotron experiments and data analysis.

Pablo Hernandez-Cerdan, Lisa Kent and other biophysics group members for the interesting discussions on parts of the project.

Chris Hall for his assistance when using the rheometer in the Riddet Institute.

I would like to thank my parents, cousins and uncles for their support and encouragement.

Finally, I would like to acknowledge New Zealand Leather and Shoe Research Association and the MacDiarmid Institute for fundings. I would also like to

acknowledge the Ministry of Business, Innovation and Employment (MBIE) for funding through grant LSRX-1301.

The SAXS experiments for this project were undertaken on the SAXS/WAXS beamline at the Australian Synchrotron, Victoria, Australia.

## **Abstract**

This thesis concerned with the interactions of surface functionalized TiO<sub>2</sub> and ZnO NPs with type I collagen. The collagen nanocomposites formed with TiO<sub>2</sub> and ZnO NPs may be potential candidates for some biomedical applications thanks to the synergetic effects between two materials. How the physical properties of collagen have been changed when interacting with TiO<sub>2</sub> and ZnO NPs has been investigated in this project. The general background and research objectives of this study are introduced in Chapter 1, followed by Chapter 2 which gives details about the preparation of the samples, in addition to the characterization techniques and protocols. The TiO<sub>2</sub> and ZnO NPs were synthesized by colloidal synthetic methods and their surfaces were functionalized with different functional groups. The physical properties of the TiO<sub>2</sub>-collagen nanocomposites and ZnO-induced collagen gels were studied by rheology, DSC, swelling ratio assay, FTIR and confocal microscopy. The mechanical studies are the main focus of this thesis.

In Chapter 3, TiO<sub>2</sub> NPs coated with chitosan and PAA were introduced into collagen solutions before fibrillogenesis was carried out. They were found to affect the linear rheology of the collagen gels as a function of their concentration. There were no significant differences in the strain-stress response in the non-linear rheology. It was found that the PAA coated TiO<sub>2</sub> NPs promoted collagen fibrillogenesis, resulting in thin fibrils, and a dense and more crosslinked structure, while the chitosan coated TiO<sub>2</sub> NPs slowed down the collagen fibrillogenesis and created a heterogeneous network with thick fibrils and less crosslinks.

ZnO-PVP NPs were found to induce collagen gelation without the use of the conventional fibrillogenesis involving gelation buffer, as reported in Chapter 4. The

hydrogel formed with this method was found to be three times as strong as the gel formed with conventional gelation buffer at the same collagen concentration. Confocal images indicated those two gels have different molecular assembly states. A group of experiments showed ZnO acted as a neutralizing agent here to raise the pH of the collagen solution to the pH close to the isoelectric point of the collagen.

Both the TiO<sub>2</sub> and ZnO NP-collagen systems have demonstrated that different collagen networks can be created by the direct or indirect interactions between collagen monomer solution and the nanoparticles. By manipulating the assembly of collagen to design different networks, it is possible to achieve the physical properties required for different applications.

The results are followed by the conclusions and future perspectives of this study.
