The Physiological Effects of Pseudoephedrine on Endurance Cycling

A thesis submitted in the partial fulfilment of the requirements for the degree of Master of Science in Sport and Exercise Science

Massey University (Palmerston North, New Zealand)

Joshua Roger Mouatt
2008
Abstract

Background: Pseudoephedrine (PSE) is a mild central nervous system stimulant that when consumed at a high dosage has the potential to alter physiological and psychophysical responses. PSE is widely accessible as over-the-counter medication and despite limited research into PSE at high dosages or its effects on prolonged exercise (>2 hours) is no-longer on the World Anti-Doping Association’s banned substance list. Currently unrestricted in sport and with no real understanding of the abovementioned responses during endurance exercise there is a high potential for abuse in sport. A recent study performed in our laboratory found PSE to improve self-paced cycling performance in some individuals, however no physiological measurements were taken.

Purpose: The primary purpose of this study was to determine the physiological effects of PSE at a dosage previously shown to improve performance (2.5 mg/kg) in some individuals during prolonged cycling. A secondary purpose of this study was to assess the effect on endurance cycling performance.

Methods: In a randomized, double-blind and counter-balanced design, ten well-trained cyclists participated in two trials, consisting of 120 min of fixed-intensity cycling at 65% $\dot{V}O_{2\text{max}}$ followed by a set work, self-paced time-trial (TT) of ~30 min, following ingestion of either 2.5 mg/kg PSE or visual-matched glucose placebo. Venous blood samples were collected before and during exercise, along with body temperatures and heart rate. Perceived effort and expired gas samples were collected during exercise. Exercise and diet was controlled ~48-hours prior to the trials.

Results: Mean heart rate was significantly higher with PSE ($P = 0.028$) during fixed-intensity exercise. Blood glucose concentrations were significantly lower with PSE ($P < 0.001$) for the first 40 min of fixed-intensity exercise. Respiratory exchange ratio was lower in the final 20-min of fixed-intensity and TT with PSE.
Blood lactate, perceived effort, ventilation, and body temperatures were not significantly different between conditions during exercise, nor was TT performance; however individual response was variable.

**Conclusions:** PSE ingestion increased heart rate during endurance cycling and initially suppressed carbohydrate release into the bloodstream while increasing fat oxidation in the later stages of exercise. Despite individual responses, endurance cycling performance remained unchanged with PSE ingestion.
Acknowledgements

First and foremost I must thank each of the participants, your enthusiasm and willingness to undergo what was a physically difficult and time consuming research trial is truly appreciated. I also wish to extend a thank you to the families of the participants, I am aware that the early morning starts and dietary requirements of the trials often required support from those at home.

Dr Toby Mündel, I cannot even begin to explain how grateful I am for your help and guidance. As a supervisor you have gone above and beyond in your commitment to this project, your unrelenting work ethic and passion for the research process has kept me in awe throughout the year and will continue to inspire me for year’s time to come.

Dr Steven Stannard, thank you for providing the research concept upon which I was able to build the study. Thank you also for your wisdom and guidance, not only for the duration of this study but in the years prior. I owe a lot of my transition from wide-eyed undergrad student to post grad study to your efforts, so thank you.

Thank you also, to Matt Barnes and Jackson Green for all your assistance both in the lab and outside with the extra jobs that come with such research projects.

To Simon Dannapfel, thank you for your suggestions and thought provoking criticisms during the writing of this thesis. Cheers buddy!

A special thanks must go to my family and friends for your continued support and innate ability to pretend to be interested as I undoubtedly bored you all to sleep explaining the intricacies of my research so many times over.

The Central Regional Health and Disability Ethics Committee (CEN/08/04/016) approved testing procedures and written consent was obtained from all participants prior to commencing the study.
