High-Pressure-Induced Starch Gelatinisation and
Its Application in a Dairy System

A thesis presented in partial fulfilment of the requirements for the Doctor of Philosophy in Food Science at Massey University, Auckland, New Zealand.

Hyunah Eustina Oh

2009
Abstract

This study investigated pressure-induced starch gelatinisation in water and milk suspensions. A rheological method, termed ‘pasting curves’, provided an objective and analytical means to determine the degree of pressure-induced starch gelatinisation. In addition, a polarised light microscope was used to observe birefringence of the starch granules and the degree of starch swelling was measured. The preliminary investigation into pressure-induced gelatinisation of six different starches showed that potato starch was the most pressure resistant and was not gelatinised after a pressure treatment of 600 MPa for 30 min at 20 °C. Waxy rice, waxy corn and tapioca starches showed complete gelatinisation after the same treatment while normal rice and normal corn starches were only partially gelatinised despite the disappearance of birefringence.

Based on the preliminary study, two starches (normal and waxy rice starches) were selected for more detailed studies. The effects of treatment conditions (pressure, temperature and duration) on the gelatinisation were investigated with these selected starches. The degree of gelatinisation was dependent on the type of starch and the treatment conditions. The results also indicated that different combinations of the treatment conditions (e.g. high treatment pressure for a short time and low treatment pressure for a longer time) could result in the same degree of gelatinisation. Both starch types exhibited sigmoidal-shaped pressure-induced gelatinisation curves and there was a linear correlation between the degree of swelling and the apparent viscosity of the starch suspension. After treatments at ≥500 MPa for 30 min at 20 °C, both starches lost all birefringence although the apparent viscosity and the degree of swelling of normal rice starch did not increase to the same extent as observed in waxy rice starch.

Pressure-induced gelatinisation of starch was retarded when starch was suspended in skim milk. This was attributed to the effect of soluble milk minerals and lactose present in the milk whereas milk proteins (casein and whey) did not affect the degree of gelatinisation at the levels present in 10% total solids skim milk. The presence of soluble milk and/or lactose may lead to less effective plasticising of starch chains by the suspension medium. Interactions between milk components and starch molecules may also play a role in retarding gelatinisation by reducing the mobility of starch chains.
The functionality of starch in a dairy application was tested using acid milk gels as a model system. Skim milk with added starch (waxy rice or potato starch) was either pressure treated (500 MPa, 20°C, 30 min) or heat treated (80°C, 30 min) and subsequently acidified to form acid milk gels. The addition of waxy rice starch resulted in firmer acid milk gels, and increasing the amount of starch caused an increase in the firmness of both pressure-treated and heat-treated samples. However, pressure-treated samples with added potato starch did not show significant changes in the firmness whereas the heat-treated counterparts showed a marked increase in the firmness as the level of potato starch increased. The difference between the effects of the two different starches can be explained by the extent of starch gelatinisation in skim milk. Starch granules absorb water during gelatinisation whether induced by pressure or heat which effectively increases milk protein concentration in the aqueous phase to form a denser protein gel network on acidification. The firmness of acid milk gels can be increased by adjusting the pH at pressure or heat treatment to higher than the natural pH of milk. The effect of pH at pressure or heat treatment and addition of starch on the acid milk gel firmness was additive and independent of each other up to a starch addition level of 1%.

This study provided an insight into pressure-induced gelatinisation of starch by showing gelatinisation properties of starches of different botanical origins and the effects of the treatment conditions (treatment pressure, treatment temperature and duration) on the degree of gelatinisation. Furthermore, the results from the pressure treatments of starch in dairy-based suspensions showed that pressure-induced gelatinisation was affected by other components in the system. These results demonstrate the importance of understanding the gelatinisation properties of starch in complicated food systems in which a number of other components are present. In terms of the application of starch in dairy systems, when starch was added to milk and gelatinised by pressure treatment, the acid milk gel produced by subsequent acidification was firmer than the acid milk gel made from skim milk alone.
Acknowledgements

It is my pleasure to acknowledge the people who made this thesis possible. First and foremost, I would like to express my utmost gratitude to my amazing supervisors: Dr. Skelte Anema (Fonterra), Dr. Marie Wong (Massey University) and Dr. Neil Pinder (Massey University). I could not have asked for a better team and I am forever grateful for all the training and encouragement you have given me over the years. I would also like to thank Dr. Yacine Hemar for his supervisory input at the earlier stage in this project.

I would like to thank everybody at Fonterra Palmerston North for having me in the lab and helping me in many ways, especially Tim Carroll for his assistance with the high pressure equipment and Liz Nickless for her technical assistance with the microscopy work.

To mum and dad, thank you for being there for me. Your love and support always kept me going even in the most challenging times.

I would also like to thank my friends for their friendship in this journey, especially, Rob Hunter for keeping my sanity (!) in the lab, Angkana Noisuwan for her company in those weekends and late nights working in the lab and Scott Hutchings and Shannon Swan for all the laughter in the postgrad office.

The financial support of the New Zealand Foundation for Research, Science and Technology (FCGL0467) and Fonterra Co-operative Group is gratefully acknowledged.

(C) Initial apparent viscosity ($\eta_{initial}$) as a function of treatment pressure (gelatinisation curves) for: waxy rice starch in (▲) water and (△) 10% TS skim milk; normal rice starch in (●) water and (○) 10% TS skim milk. All pressure treatments were carried out at 20 °C for 30 min……………………………………………………………………………………………………………………6-5

Fig. 2: Initial apparent viscosity ($\eta_{initial}$) as a function of treatment pressure within the gelatinisation pressure range for (A) waxy rice starch and (B) normal rice starch (10% w/w), and degree of swelling as a function of treatment pressure within the gelatinisation pressure range for (C) waxy rice starch and (D) normal rice starch in various suspension media containing: (●) water only; (○) soluble milk minerals; (▲) soluble milk minerals and lactose; (△) soluble milk minerals, lactose and casein micelles; (■) 10% TS skim milk. (E) Plot of initial apparent viscosity ($\eta_{initial}$) versus degree of swelling (%) for (○) waxy rice starch and (●) normal rice starch, all suspension media. All pressure treatments were carried out at 20 °C for 30 min………………………………………………………………………………………………………………6-6

Fig. 3: Pasting curves of (A–E) waxy rice starch (10% w/w) after (●) no pressure treatment, (○) pressure treatment at 400 MPa and (▲) pressure treatment at 600 MPa and (F–J) normal rice starch (10% w/w) after (●) no pressure treatment, (○) pressure treatment at 450 MPa and (▲) pressure treatment at 600 MPa in various suspension media containing: (A, F) water only; (B, G) soluble milk minerals; (C, H) soluble milk minerals and lactose; (D, I) soluble milk minerals, lactose and casein micelles; (E, J) 10% TS skim milk. All pressure treatments were carried out at 20 °C for 30 min…………………………………………………………...6-7

Fig. 4: Polarised light micrographs of (A–E) waxy rice starch after pressure treatment at 400 MPa and (F–J) normal rice starch after pressure treatment at 450 MPa in various suspension media containing: (A, F) water only; (B, G) soluble milk minerals; (C, H) soluble milk minerals and lactose; (D, I) soluble milk minerals, lactose and casein micelles; (E, J) 10% TS skim milk. All pressure treatments were carried out at 20 °C for 30 min………………………………………………………………………………………………………………6-9

Figure 7-1: Block diagram of acid gelation experiments………………………………………………………………………………………………………………7-2

Fig. 1: A. Change in pH with time after GDL addition for (●) heated milk with 0% potato starch and (○) heated milk with 1.5% potato starch. B. Change in storage modulus, G', at 30 °C, with time after GDL addition: (□) unheated milk; (●) heated milk with 0% potato starch; (○) heated milk with 0.25% potato starch; (▲) heated milk with 0.5% potato starch; (△) heated milk with 1% potato starch; (■) heated milk with 1.5% potato starch. C. Final value of the storage modulus, G', at 30 °C as a function of the starch addition level. Error bars represent standard deviations…………………………………………………………………………………7-8
Fig. 2: Storage modulus, $G'$, and loss modulus, $G''$, of final acid gels at 5 °C as a function of frequency for acid milk gels containing (●) 0%, (▼) 0.25%, (■) 0.5%, (▲) 1% and (▲) 1.5% potato starch. Open symbols are for $G''$ and solid symbols are for $G'$.…………………………………………………………………..7-9

Fig. 3: A. Storage modulus, $G'$, as a function of temperature for acid milk gels containing (●) 0%, (▼) 0.25%, (▲) 0.5%, (▼) 1% and (■) 1.5% potato starch. Inset: plot of $G'/G'$ at 5 °C versus 1/$T$ for the same acid milk gels. B. Loss modulus, $G''$, as a function of storage modulus, $G'$, for acid milk gels at (●) 30 °C and (○) 5 °C……………………………………………………………………7-10

Fig. 4: A. Stress as a function of strain for acid milk gels containing (●) 0%, (○) 0.5%, (▼) 1% and (▼) 1.5% potato starch. B. Breaking stress (○) and breaking strain (●) of acid milk gels as a function of potato starch concentration. Error bars represent standard deviations. Data points with the same letter are not significantly different ($P<0.05$) as determined by ANOVA……………………...7-11

Fig. 5: CSLM micrographs of final acid milk gels containing (A) 0%, (B) 0.5%, (C) 1% and (D) 1.5% potato starch. The bar corresponds to 20 µm……………………………...7-12

Fig. 1: (A) Shear stress as a function of shear rate for milk heated at pH 6.64 with (●) 0%, (○) 0.5%, (▼) 1% and (■) 2% potato starch. (B) Apparent viscosity as a function of starch addition level at the shear rate of 100 s⁻¹ for milk heated at: (●) pH 6.5; (▼) pH 6.64; (■) pH 6.9………………………….7-15

Fig. 2: Changes in storage modulus, $G'$, after GDL addition as a function of time at 30 °C for milk with 0% (A) and 1% (B) potato starch heated at: (●) pH 6.5; (○) pH 6.6; (▼) pH 6.64; (▼) pH 6.75; (■) pH 6.9; (□) pH 7.1. Error bars represent standard deviations of repeated measurements……………………………….7-16

Fig. 3: (A) Final value of the storage modulus, $G'$, and (B) ratio of final $G'$ value at a given pH to final $G'$ value at pH 6.5 for milk with (●) 0%, (○) 0.5%, (▼) 1%, (▼) 1.5% and (■) 2% potato starch at 30 °C as a function of the pH at heating. Error bars in Fig. 2A represent standard deviations of repeated measurements. Error bars in Fig. 2B represent pooled standard deviations……………...7-17

Fig. 4: Stress as a function of strain for acid milk gels containing 0% (A) and 1% (B) potato starch. Milk heated at: (●) pH 6.5; (▼) pH 6.64; (■) pH 6.9. (C) Breaking stress and breaking strain of acid milk gels as a function of starch addition level. Milk heated at: (●, ○) pH 6.5; (▼, ▼) pH 6.64; (■, □) pH 6.9. Filled symbols for strain and open symbols for stress. Error bars represent standard deviations of repeated measurements……………………………….7-18

Fig. 5: CSLM micrographs of final acid milk gels: heated at pH 6.5 and containing 0% (A) and 1% (C) potato starch; heated at pH 6.9 and containing 0% (B) and 1% (D) potato starch. The bar corresponds to 20 µm…………………………………………………7-19
In manuscript, Oh, H. E., M. Wong, D. N. Pinder, and S. G. Anema. "Comparison of pressure treatment and heat treatment of skim milk with added starch on subsequent acid gelation of milk"

Figure 7-2: Acid gelation curves of (A) milk samples with waxy rice starch after pressure treatment (500MPa / 20°C / 30min), Inset: Final G'$_{30°C}$ as a function of waxy rice starch addition level, (B) milk samples with waxy rice starch after heat treatment, (C) milk samples with potato starch after pressure treatment, Inset: Final G'$_{30°C}$ as a function of potato starch addition level and (D) milk with potato starch after heat treatment (80°C / 30min) at addition levels (●) 0%, (○) 0.5%, (▲) 1% and (△) 1.5% (w/w). The pH at treatment was pH 6.64 (natural). Error bars represent standard deviations of repeated measurements.7-32

Figure 7-3: CSLM micrographs of final acid milk gels made from pressure-treated milk (500MPa / 20°C / 30 min; A, C, E) and heat-treated milk (80°C / 30 min; B, D, F). A, B: with no added starch; C, D: with 1% waxy rice starch; E, F: with 1% potato starch added prior to treatment.7-35

Figure 7-4: Polarised light micrographs of milk samples before acidification with 1% waxy rice starch (50×) (A, C, E), and 1% potato starch (20×) (B, D, F) added prior to pressure or heat treatment. (A, B) untreated, (C, D) pressure-treated at 500MPa and 20°C for 30 min and (E, F) heat-treated at 80°C for 30 min.7-37

Figure 7-5: Acid gelation curves for (A) pressure-treated (500MPa / 20°C / 30 min) milk samples (B) heat-treated (80°C / 30 min) milk samples at pH 6.5 (●) with no added starch and (○) with 1% waxy rice starch; at pH 6.64 (natural) (▲) with no added starch and (△) with 1% waxy rice starch; at 6.9 (■) with no added starch and (□) with 1% waxy rice starch. (C) Final G'$_{30°C}$ as a function of pH at treatment. (●) no added starch, pressure-treated, (○) 1% waxy rice starch, pressure-treated, (▲) no added starch, heat-treated and (△) 1% waxy rice starch, heat-treated. Error bars represent standard deviations of repeated measurements.7-39

Figure 7-6: CSLM micrographs of final acid milk gels made from milk samples pressure-treated (A) at pH$_{pressure}$ 6.5 with no added starch and (B) at pH$_{pressure}$ 6.9 with no added starch, (C) at pH$_{pressure}$ 6.5 with 1% waxy rice starch and (D) at pH$_{pressure}$ 6.9 with 1% waxy rice starch added prior to pressure treatment (500MPa / 20°C / 30 min).7-41

List of Symbols

$\eta_{\text{initial}}$  Apparent viscosity at 20 °C before pasting begins

$\eta_{\text{peak}}$  Maximum apparent viscosity attained during pasting

$T_{\text{onset}}$  Onset temperature of gelatinization at which the apparent viscosity starts to increase

$T_{\text{peak}}$  Temperature at $\eta_{\text{peak}}$

$G'$  Storage modulus

$G''$  Loss modulus

List of Abbreviations

CCP  Colloidal calcium phosphate

GDL  Glucono-δ-lactone
