Master of Science

In
Conservation Biology

at Massey University, Palmerston North, New Zealand

Rebecca Kay French
2018
Abstract

Eco-tourism is increasing in popularity worldwide, particularly in previously isolated areas such as Antarctica and the subantarctic. This may be increasing the levels of human disturbance stimuli (human-related presence, objects or sounds), which can have impacts on wildlife at an individual level (behaviourally and physiologically) and at a population level. Human disturbance (the response of an animal to a disturbance stimulus) has been studied in most penguin species, showing both inter- and intra-specific differences in responses to disturbance stimuli at similar distances. The Yellow-eyed Penguin (*Megadyptes antipodes*) is negatively impacted by human disturbance stimuli, but very little research of any kind has been conducted on the subantarctic population. This is despite some areas within the subantarctic being regularly exposed to tourism, and the subantarctic population making up an estimated 60% of the entire species. I used an experimental approach to investigate the behavioural impacts of human disturbance stimuli on subantarctic Yellow-eyed Penguins, on Enderby Island. Human presence significantly changed their behaviour, resulting in an increased time spent vigilant and a decrease in the frequency of maintenance behaviours. By modelling the probability of disturbance at varying distances from the penguin to the human, I showed the current minimum approach distance of 5 m (with a 99% chance of disturbance) was not effective. I also quantified the breeding biology of subantarctic Yellow-eyed Penguins, and investigated the impact of human disturbance stimuli on their breeding success. There was no difference in nesting success (expressed as number of eggs, chicks and fledglings surviving per pair) between the disturbed and undisturbed site and no significant difference in the average weight and body size of fledglings at the disturbed site compared to fledglings at the undisturbed site. My results indicate that at current levels human disturbance stimuli has a behavioural impact on subantarctic Yellow-eyed Penguins, but a population-level impact was not detectable. This may be due to the low level of tourism and high degree of tourism management in the New Zealand...
subantarctic, and the resulting low number of interactions between penguins and humans. Enderby Island tourism may therefore be an example of sustainable eco-tourism and successful management, although more research including multi-year studies would be needed to confirm this.
Acknowledgements

I would firstly like to say a huge thank you to my primary supervisor Phil Battley. I feel very lucky to have had such a knowledgeable, supportive and approachable mentor! Thank you for all the advice, guidance and support. I would also like to say a big thank you to my co-supervisor Louise Chilvers, for her very helpful feedback throughout the process.

This thesis would not have been possible without Chris Muller – thank you for your unwavering support, your confidence in me and all the help you gave me from beginning to end. Thank you for keeping me sane during those long months on Enderby. I am also particularly grateful for all the freezing cold evenings you spent out in the rain and wind being my ‘human disturbance’, after long days in the field!

I am grateful to Mel Young, Trudi Webster, Jim Fyfe, Simon Childerhouse, Tony Preston and Jo Hiscock for your assistance and advice. Thank you to Sharon Trainer and Rory Hanan for all your help at the Quarantine store. Thank you to Steve Kafka and the crew of Evohe, and the HMNZS Otago for safely transporting us through the Furious Fifties. Thank you to Shannon Taylor for your support, and for helping with field work. Thank you to the New Zealand Department of Conservation for logistical, funding and practical support including transport to the island, and providing essentials including food and the loan of equipment. Thanks also to the following for supplying equipment: Ecology Group Massey University, Yellow-eyed Penguin Trust and Blue Planet Marine. I am also grateful for the funding provided by a Massey University MSc Scholarship, Birds New Zealand Research Fund, and Massey University Ecology Group Scholarship.

Finally, I am very grateful to my family. A big thank you to my parents – you have been, and always will be a huge source of inspiration to me, and I am so proud to be your daughter.

List of Tables

**Table 1.1.** Details of each tour boat expedition that landed on Enderby Island in the 2016 – 2017 season: Date, Company, Maximum number of tourists on each boat (Max Pax). ........................................ 18

**Table 2.1.** Current published literature on behavioural, physiological and population-level impacts on wild penguins. Number of publications for each species is listed by the result - as either habituation (defined as a reduced response to disturbance stimuli following previous exposure), negative, or 'none detected' (where no statistically significant impact was detected). Literature is counted more than once where multiple responses or species are studied within one paper. ........................................................................................................ 50

**Table 4.1.** Estimated age based on chick appearance, used to determine hatch dates. Based on previous research (Darby & Seddon 1990; van Heezik & Davis 1990). .................................................. 81

**Table 4.2.** Linear regression equations, p-values and R-squared values for fledging weight, skull length and foot length at the undisturbed site (Rocky Ramp) and the disturbed site (Sandy Bay). ......................................................................................................................................... 82

**Table 4.3.** Total and average number of eggs laid, chicks hatched and fledglings (chicks that survived to mid-February) for the Rocky Ramp (RR) site (no disturbance stimulus present, n=27) and Sandy Bay (SB) site (disturbance stimuli present, n=17) and all nests (n=49). ‘All’ is the total, including ‘hybrid’ nests (where one parent used Rocky Ramp and one Sandy Bay, n=3) and nests where the landing site of the parent(s) was unknown (n=2). Model results are the Z values (degrees of freedom) and p-values of the generalised linear models for the effect of site (with site as the predictor variable). Hybrid nests and nests where the landing site is unknown were excluded from this analysis. Only nests with known hatch dates are displayed in this table and were used in the model. ............................................................................... 88

**Table 4.4.** Model results from the linear mixed model Chick Size ~ Chick Weight + Brood-size + Habitat + Overhead nest cover + Site + (1 |Nest ID). ............................................................. 88

**Table 4.5.** Model results from the linear mixed model Chick Mass ~ Site*Overhead nest cover*Nest habitat + Brood-size + fledging body size + (1 |Nest ID). ........................................................ 89

**Table A.1.** Current published literature on behavioural, physiological and population-level impacts on wild penguins. The key results of each paper are summarised under 'outcome' as either habituation (defined as a reduced response to disturbance stimuli following previous exposure), negative, or 'none detected' (where no statistically significant impact was detected). Literature is counted more than once where multiple responses or species are studied within one paper. ........................................................................................................ 50
detected). Literature is listed more than once where multiple responses, species or disturbance stimuli are studied within one paper. UAVs are unmanned aerial vehicles.
