Practical Aspects of Phytoextraction

A thesis presented in partial fulfilment of the requirements for the degree of

Doctor of Philosophy
in
Earth Science

Christopher William Noel Anderson

2000

Massey University
Palmerston North
New Zealand
APPLICATION FOR APPROVAL OF REQUEST TO EMBARGO A THESIS
(Pursuant to AC 98/168 (Revised 2), Approved by Academic Board 16.02.99)

Name of Candidate: Christopher W. N. Anderson  ID Number: 93000196
Degree: PhD  Dept/Institute/School: Institute of Natural Resources
Thesis Title: Practical Aspects of Phytoextraction
Name of Chief Supervisor: Prof. R. R. Brooks  Telephone Extn: 7023

As author of the above named thesis, I request that my thesis be embargoed from public access until (date) 1st of April 2002 for the following reasons:

☐ Thesis contains commercially sensitive information.
☐ Thesis contains information which is personal or private and/or which was given on the basis that it not be disclosed.
☐ Immediate disclosure of thesis contents would not allow the author a reasonable opportunity to publish all or part of the thesis.
☐ Other (specify):

Please explain here why you think this request is justified:

This thesis contains unpublished information that describes in detail the steps necessary to effect the phytoextraction of gold using induced hyperaccumulation. Ongoing research is investigating the economic potential of this technology. The information contained within this thesis will remain commercially sensitive until this period of research has been completed.

Signed (Candidate): ___________________________ Date: 18/2/00
Endorsed (Chief Supervisor): ___________________________ Date: 18/2/00
Approved/Not Approved (Representative of VC): ___________________________ Date: 20/02/00

Note: Copies of this form, once approved by the representative of the Vice-Chancellor, must be bound into every copy of the thesis.
Abstract

Phytoextraction for heavy metals is an emerging technology that has potential application for the remediation of many contaminated sites around the world. The technology has similar application to the mining of low-grade ore bodies. Several practical aspects of the technology are addressed in this thesis.

Natural and induced-uptake phytoextraction trials have been conducted on two contaminated substrates: an area of industrial pollution in northern France, where base metals are present in an oxide and carbonate mineral phase, and an area of mine tailings in New Zealand, where base metals are present in a sulphide or sulphate mineral phase. The uptake response of several hyperaccumulator and non-accumulator plant species is described. Geochemical models are then presented that explain the observed metal uptake as a function of the predominant chemical form of metal present in the soil. Natural uptake is dependent upon the form of metal. It appears that the relative efficacy of various hyperaccumulator species to accumulate metals is also dependent upon site-specific geochemistry. The efficacy of chelating agents, in particular EDTA, to induce uptake is similarly dependent upon the chemical form of metals in the soil.

A field trial for cadmium phytoextraction was conducted on an area of pastoral land contaminated with this metal due to the application of cadmium to soil through superphosphate fertilisation. Natural uptake at this site by the hyperaccumulator species *Thlaspi caerulescens* could remove the equivalent of 17 years of annual cadmium application in one harvest. The chelating agent EDTA (ethylenediaminetetraacetic acid) did not induce significant uptake by the non-accumulator *Brassica* species. Instead, the action of this chemical was to redistribute 14% of the cadmium initially present in the 0-5 cm soil depth to the 5-10 cm depth, and to leach approximately 4% of the cadmium initially present at the site to below 10 cm in the soil profile, as shown by mass balance calculations. Phytoextraction effected by *T.caerulescens* is proposed as a management tool for cadmium in the pastoral environment.
Phytoextraction for nickel has been investigated at a field site in the central North Island of New Zealand. Hyperaccumulation was effected by two *Alyssum* species and by *Berkheya coddii*. However, the biomass of the harvested plant material was below that reported in the literature. The conclusion from this trial is that substrate modification of ultramafic soil may be necessary before phytoextraction for nickel could be implemented.

A significant obstacle hindering the practical application of phytoextraction in some environments, is the paucity of hyperaccumulator species that are native to some parts of the world. Western Australia has many sites that may benefit from phytoextraction for nickel. However, only one hyperaccumulator species is native to this region, *Hybanthus floribundus*, a species that has in the past been difficult to germinate from seed. This thesis describes a successful approach to germination, involving the use of one-year-old seeds, treated with ‘Regen 2000 smoke water’ and germinated under dark conditions, that may overcome this practical aspect (a limitation) of phytoextraction technology.

The most recent advance of induced phytoextraction technology has been the thioligand-induced uptake of gold by plants. The initial discovery and the geochemical rationale behind the induced uptake of gold is described. The maximum gold uptake presented is accumulation of 57 mg/kg dry weight gold by *Brassica juncea* and it is proposed that this level of uptake could make the phytomining of gold from tailings areas an economic proposition.

The conclusion of this thesis is that potential for the implementation of phytoextraction is large. Globally, the technology could offer an environmentally and economically friendly alternative to the traditional decontamination of metals from some sites. There is also potential for the phytomining of metals from low-grade ores. The social implications of phytoextraction technology in third-world countries could also be large. Phytoextraction for gold, for example, from auriferous tailings in Africa and South America, has the potential to improve both the environment and the standard of living of the local communities who live off contaminated land.
Acknowledgements

I would like to express my sincere thanks to my supervisors. Firstly to Professor Robert Brooks, under whose guidance I feel privileged to have had the opportunity to study metal uptake by plants. Also to Bob Stewart and to Robyn Simcock for keeping me honest and on track to finish within time, and for pulling in the reins when I would slip out of control!

I would like to express my thanks to the Agricultural and Marketing Research and Development Trust (AGMARDT) for funding this project through the award of a doctoral scholarship.

I thank Professor Daniel Petit from the University of Lille in northern France who made possible my time researching metal uptake in Europe. I also express my deepest thanks to Annabelle Deram and Valerie Bert from Lille whose friendship made my time there so enjoyable.

I acknowledge the support of the Western Mining Company Ltd. of Australia, in particular Colin Woolard, Tara Read, Bonny Nicholson and Frances Mills for making possible the Australian part of the project and for showing me the ‘wild’ ways of Western Australia.

I am greatly indebted to other agencies for their financial support of this project. To the New Zealand Vice Chancellors’ Committee for the award of a Claude McCarthy Fellowship which enabled me to attend the ICObTE conference in Vienna and the PACRIM conference in Bali during 1999. To the graduate research fund for making travel and field trials possible. To the Massey University Ag-hort faculty for the award of a Helen E. Akers scholarship in 1998.

I thank most sincerely Mr. Don Adams from Blairlogie, Wairarapa whose assistance made possible the Wairarapa cadmium field trial.

I also thank Mr. Peter Strongman from Rorison Mineral Developments Ltd. of Piopio whose assistance made possible the Piopio nickel field trial.

I say a big thank you to all the staff and students, past and present, who have supported me through my years in the Soil Science Department. Five years ago I swore I was never going to complete Honours let alone a PhD! The value of the advice, encouragement and assistance that goes with being part of a good department cannot be measured.

I would like to thank all my friends outside of Massey, who have put up with me through good times and bad over the course of my studies.

Finally, I would like to acknowledge and express my deepest thanks to my family for their encouragement and support as I became interested in science from an early age.

Table 11.3. Induced uptake of gold by Brassica juncea grown on Waihi gold ore. 

Table 11.4. Selected summary of thiocyanate (SCN')-induced uptake of gold for various plant/substrate combinations. 

Table 11.5. Comparison of Tui tailings samples collected from three locations within the TSF illustrating the broad range of SCN-extractable gold values that can be observed. 

Table 11.6. Comparison of the total and extractable gold concentrations for Tui JWM with selected substrates on which plant trials have been conducted. 

Table 11.7. pH and micronutrient concentrations of bulk and rhizosphere soil of white lupin (Lupinus albus) grown in a phosphorus deficient soil. 

Table 12.1. Number of crops of Berkheya coddii required to reduce the nickel contamination in soil to the European Union guideline of 75 mg/kg. 

Table 12.2. Comparative toxicity of 4 sodium salts that can solubilise gold and may be used for induced hyperaccumulation.
