An Investigation into the Presence of Seasonal Symptoms in a Sample Treated for Depression

A thesis presented in partial fulfillment of the requirements for a degree of Doctorate of Clinical Psychology

at Massey University, Albany, New Zealand

Susan Page
2011
Abstract

The “winter blues” would appear to be a global concept. This thesis examined features of depression, seasonal change and meteorological data in relation to theories on the development of seasonal depression and Seasonal Affective Disorder (SAD). It reviewed the neurotransmitter based theories of causation where increased exposure to light is thought to stimulate normal neurotransmitter production. It also examined the dual vulnerability hypothesis (DVH) which postulated that vegetative symptoms arose from a different vulnerability than depressive symptoms. Levels of vegetative symptoms and depression were analysed in relation to the different climate experienced in Auckland, New Zealand. Three studies were undertaken. In the first study, the sample consisted of 195 individuals in New Zealand who self-referred to participate in a separate research project examining the effects of “homework” and cognitive behavioural therapy for first time depression. Meteorological data were investigated in order to explore any potential vulnerability to seasonal depression in this sample. Additionally, age and gender were explored in relation to season of presentation. The second study involved the subsample \((n = 81)\) who were assessed for therapy and examined season and symptom profile in relation to when the person presented. The third study traced the progress through therapy of 28 adults who were selected from the second study for CBT. The Beck Depression Inventory (BDI-II) provided additional data to test the related hypotheses. Rate of change in depression scores and symptom expression in relation to seasonality were analysed using multilevel modelling (MLM). Daily hours of bright sunlight was found to have an unusual relationship to temperature in New Zealand when compared with previous research. In this setting increased sunshine was associated with lower temperatures. Therefore, the variables were separated in order to ascertain whether one affected results more than others. Bright sunshine hours affected the expression of vegetative symptoms with a decrease observed over time in relation to increased photoperiod. Subtle relationships between temperature and vegetative symptoms were observed. However, there was an overall lack of correlation between vegetative and depressive symptoms observed in the CBT sample, and sunlight was not observed to have any effect on typical depressive symptoms. The investigation provided partial support for the neurotransmitter basis of vegetative symptoms and for the dual vulnerability hypothesis. Gender and age were correlated with vegetative symptom endorsement, although over time only gender was found to have any ongoing significance in the presentation of seasonal symptoms with women more likely to exhibit vegetative responses over time.
Acknowledgements

I wish to thank a number of people who have been influential in this project over the last few years.

Firstly, I would like to thank my main supervisor Dr Dave Clarke, for his consistent, helpful feedback and ongoing support. Also, Dr Dianne Gardner who kindly became my supervisor at late notice part-way through this process, and who has provided her expertise in a number of areas. Additionally, I would like to acknowledge Dr Richard Fletcher for his help with multi level modelling, and Dr Nikolaoas Kazantzis for his feedback and supervision, during the first part of this project. I would also like to acknowledge Dr Kazantzis and Ms Robin Vertongen for their clinical supervision and training during the research study. Additionally, I would like to acknowledge the contributions of my colleagues involved the research study used in this project for their support, timely advice and dedication.

Finally, but not least I would like to acknowledge the support and commitment of my family who have made this journey with me. To my husband Tim and our children Sam and Abby a heartfelt thank you I could not have made it without your love, kindness and sacrifice when I was writing and showing you my graphs. Also to my parents who provided various articles involved in the formulation of this topic and their practical support over this journey.
