EFFECTS OF RDI ON APPLE TREE (cv. Royal Gala) GROWTH, YIELD AND FRUIT QUALITY IN A HUMID ENVIRONMENT

A thesis presented in partial fulfilment of the requirements for the degree of Doctor in Philosophy in Horticulture at Massey University

Gladys Durand
November, 1990
To my Beloved Son Kahlil
who fills my life with joy

and In Memory of my Husband.
ABSTRACT

The feasibility of using Regulated Deficit Irrigation in the humid environment of New Zealand was evaluated on trees of apple cv. Royal Gala (*Malus domestica* Borkh.). The study was carried out in a glasshouse experiment and a field experiment. In the glasshouse experiment, it was evaluated the pattern of soil water extraction by the winter mutant of lucerne (*Medicago sativa sensu lato*) ASR13R from a 'synthetic' soil layered in the same way that it occurs in the research orchard, under trickle and sprinkler irrigation. Results indicated that lucerne extracted soil water at a high rate and explored deep areas of soil.

The field experiment was conducted during two consecutive seasons (1987-1989). Lucerne as under tree cover and black polyethylene mulch were compared with conventional herbicide strip to control excess of water in the root zone of the crop that would otherwise promote vegetative growth. These treatments were applied in combination with an irrigation schedule divided into three Phases. In Phase I, water was withheld, in Phase II RDI was compared with full irrigation, and during Phase III which coincided with the rapid fruit growth, all treatments received the full irrigation rate. During the first season, RDI and full irrigation treatments were based on 25% and 100% replacement EPS (evaporation in the planting square) respectively. In the second season, after a 50% of the soil water content in the top 600 mm of soil, between Drainage Upper Limit and the Lower Limit was reached, full irrigation treatments were replenished to the DUL, while RDI treatments received 25% of that amount. Results showed that under the conditions of this study evaluation of crop water requirements based on soil moisture measurements was more reliable than those based on pan evaporation.

The degree of reduction of summer pruning obtained under lucerne X RDI treatment,
reflected levels of soil and plant water deficit similar to those obtained in arid environments. Results confirmed my hypothesis that by using lucerne as under tree cover, a RDI strategy can be used in this environment. In contrast, black plastic mulch appeared to maintain soil moisture rather than prevent its accumulation. Nevertheless, effects were obtained which reflected positively in fruit growth and yield. Similar results were obtained under the control treatment, although it was less effective for in reducing tree vigour. The latter treatment, however, can be implemented in most orchards at no cost and generate important savings.

Apple fruit growth proved to be relatively insensitive to water deficit imposed during early stages of growth, whereas vegetative growth was checked. Restoring full irrigation to coincide with rapid fruit growth stimulated growth of RDI fruits resulting in higher yield under control and plastic X RDI. Lucerne showed higher rates of water use that were not compensated by the irrigation which affected fruit growth and size. Results showed that fruits from RDI treatments were firmer, accumulated higher T.S.S. and had lower bruise susceptibility than fruits from fully irrigated treatments. Fruit quality remained higher after 10 weeks of cool storage.
ACKNOWLEDGMENTS

I am greatly indebted to Professor David Chalmers for the tremendous effort and time he spent in guiding this work and preparing the manuscript. Thanks for his constant moral support and the encouragement to venture in the applied Plant Physiology field.

Gratitude is extended to Dr. Brent Clothier, DSIR for his invaluable assistance with the soil data:

Thanks to the New Zealand Government, Ministry of External Relations and Trade, Venezuelan Government and mainly to Massey University for the scholarship grant;

Grateful acknowledgments are due to Dr. Hugo Varela for all the efforts in solving the most complicated computer programming of this work and for his "latin" friendship.

I am very grateful to the staff and postgraduate students, Department of Horticultural Science at Massey University, for their help throughout this study.

Special thanks are extended to Simon Cayzer and Andrew Saunders for their assistance during the field work and to Bruce MacKay and Dr. Preston Andrew for their constructive comments and suggestions.

Thanks to all the staff of Fruit Crop Unit for their enormous help during the experimental work.

Thanks to the Filipino and Singaporean communities and all my friends in New Zealand, for "replacing" my family when far from home.
My deep appreciation goes to my brothers and sisters for their great moral support and love, and especially to my mother who extended her unfailing love support to me and my work.

Finally, I give thanks to the Lord Jesus who guided my steps to the stage where I am.

5.2. Seasonal pattern of soil water stored (W) under plastic treatments, estimated by the neutron probe. ................. 170

5.3. Seasonal pattern of soil water stored (W) under control treatments, estimated by the neutron probe. ................. 171

5.4. Seasonal pattern of soil water stored (W) under lucerne treatments, estimated by the neutron probe. ................. 172

5.5. Cumulative soil water deficit obtained under plastic treatments during the growing season 1988-1989 ............... 176

5.6. Cumulative soil water deficit obtained under control treatments during the growing season 1988-1989 ............... 177

5.7. Cumulative soil water deficit obtained under lucerne treatments during the growing season 1988-1989 ............... 178

5.8. Seasonal pattern of predawn ($\Psi_{Lp}$) and midday ($\Psi_{Lm}$) leaf water potential for plastic treatments .................. 183

5.9. Seasonal pattern of predawn ($\Psi_{Lp}$) and midday ($\Psi_{Lm}$) leaf water potential for control treatments .................. 184

5.10. Seasonal pattern of predawn ($\Psi_{Lp}$) and midday ($\Psi_{Lm}$) leaf water potential for lucerne treatments .................. 185

5.11. Seasonal pattern of predawn stem water potential ($\Psi_s$) of control X full irrigation and lucerne X RDI treatments ................................................................. 190

5.12. Seasonal pattern of midday stem water potential ($\Psi_s$) of control X full irrigation and lucerne X RDI treatments ................................................................. 191

5.13. Accumulated shoot growth for all the treatments from day 47 to 104 after full bloom ........................................ 195

5.14. Ratio fruit growth rate of RDI treatments to the respective full irrigation treatments ........................................ 195
5.15. Change in fruit volume of Royal Gala apple trees as affected by treatments during the season 1988-1989. .................. 199
5.12. Seasonal pattern of midday stem water potential ($\Psi_s$) of control X full irrigation and lucerne X RDI treatments.

5.13. Accumulated shoot growth for all the treatments from day 47 to 104 after full bloom.

5.14. Ratio fruit growth rate of RDI treatments to the respective full irrigation treatments.

5.15. Change in fruit volume of Royal Gala apple trees as affected by treatments during the season 1988-1989.
