“The greatest benefit of dag control or elimination may come from reduced fly strike” V. J. Mackereth (1983), an astute breeder.

Abstract

Pickering, N. K. (2013). Genetics of flystrike, dagginess and associated traits in New Zealand dual-purpose sheep. PhD thesis, Massey University, Palmerston North, New Zealand.

A literature review identified breech bareness, dagginess and fibre traits as potential indirect indicator traits for flystrike. Dagginess (faecal accumulation) had the greatest potential as an indirect indicator, and has been identified as an important trait itself. Therefore flystrike and dagginess were investigated for their associations with fibre and production traits. A genome-wide association study (GWAS) was performed to identify regions under selection and associated with these traits. Finally, a genomic selection (GS) analysis was performed for dagginess and dual-purpose production traits to estimate molecular breeding values (MBVs) and to determine their impact on the New Zealand dual-purpose selection index.

Heritability, genetic and phenotypic parameter estimations were performed on a flystrike case-control dataset collected over 2 years. Flystrike had a heritability of 0.37, and high genetic and phenotypic correlations with dag score and a high genetic correlation with the coefficient of variation of fibre diameter. A similar analysis was performed on an existing New Zealand sheep industry dataset of about 2 million pedigree-recorded animals born between 1990 and 2008. The heritability for dag score at 3 and 8 months (DAG3, DAG8) was 0.34 and 0.31 respectively. There were low or nil genetic and phenotypic correlations of DAG3 and DAG8 with the other standard live weight, fleece weight, reproduction and faecal egg count production traits or breech bareness, fibre and wool traits.

A GWAS performed on an industry dataset of 8,705 genotyped animals, using phenotype information on about 3 million pedigree-recorded animals, identified regions on chromosome 6 and 15 associated with DAG3 and DAG8. The lambs from the flystrike case-control dataset with SNPs imputed from 5K to 50K identified a number of immune, diarrhoea and wool/hair growth genes associated with flystrike, dag score and fibre traits in a GWAS. There were no similarities in the genes identified in the industry or case-control GWAS; however, the SNP on chromosome 15 was re-identified in the GS analysis for DAG8. The GS analysis showed that genomic predictions can be

Genetics of flystrike and dagginess in New Zealand dual-purpose sheep

performed for DAG3 and DAG8 and that using MBVs and modifying generation interval can increase the rate of the genetic gain of the dual-purpose index by 84% per year.

Acknowledgements

At least 4 years ago and maybe back the full 28 years, I have had the guidance of a forward thinking father who did not want to crutch another sheep. Also along the last 6 years I have had the opportunity to work with another forward thinking and supportive, first boss then supervisor, John McEwan. Together I have them to thank for one suggesting the topic and the other in moulding my scientific skills so as to answer the question “Can I breed for no dags and flystrike?”

There are a number of people who I’ve had the opportunity to work with and learn off during this experience. Firstly my full contingent of supervisors: Hugh Blair, Rebecca Hickson from Massey University and Tricia Johnson and John McEwan from AgResearch, Invermay. Thank you for your contributions to shaping me, my experiments, and my thesis. Also for teaching me ‘past and present’ tense. I would also like to thank Ken Dodds and Benoit Auvray for their guidance and invaluable help with the statistical component of the project, without them the languages, programs and methods such as R, SAS, ASReml, genomic selection and GWAS would still be foreign outer space ‘things’! I’ve also had the pleasure of sharing my workspace with the Invermay Animal Genomics team, some have come and gone since I first started at AgResearch, but all have contributed to the great atmosphere which has been a pleasure to work in.

Secondly, the financial support of Ovita and AgResearch for funding the research and for the provision of my doctoral stipend. Also the IVABS Travel Award, Early Career Scientist Travel Bursary, and the Charles Elgar Scholarship awards which have allowed me to attend and/or present my work at 9th World Congress on Genetics Applied to Livestock Production (2010), The Applied Genomics for Sustainable Livestock Breeding Conference (2011), New Zealand Society of Animal Production (2012), and the 32nd and 33rd International Society of Animal Genetics (2010, 2012) conferences.

Thirdly, this project would not be possible without the support of the farmers that have allowed me access to their flocks via SIL and have allowed me to look at ~ 30,000 dirty and clean lamb bottoms. Also the efforts of those that collected samples and measurements of flystruck lambs for me, a not very pleasant job, were very much

Genetics of flystrike and dagginess in New Zealand dual-purpose sheep

appreciated. A big thank you for those that provide me a bed and great home cooking during my road trips around the country collecting measurements; these provided some of my most memorable moments during my project.

A big thank you to my family; Mum, Dad and brothers for their amazing support throughout my life, and helping me through the PhD by being a willing participant in the case-control study. Finally to Jason, who has been a rock for me for the past 3 years, putting up with my stressed out moments and encouraging me to try new things like scuba diving.

I thank you all.

- Figure 8.1:** The first 4 principal components (PC) calculated from all animals for weaning weight. Romney (blue), Coopworth (green), Texel (yellow), Perendale (purple) and others/composites (grey) 242
- Figure 8.2:** Manhattan plot of $-\log_{10}(P)$ values of SNPs for weaning weight. Ordered on the ovine genome v2 map, $P < 0.0001$ (solid red line), $P < 0.001$ (red dash line) 251
- Figure 8.3:** Manhattan plot of $-\log_{10}(P)$ values of SNPs for fleece weight at 12 months. Ordered on the ovine genome v2 map, $P < 0.0001$ (solid red line), $P < 0.001$ (red dash line) 251

- Figure 8.4:** Manhattan plot of $-\log_{10}(P)$ values of SNPs for dag score at 3 months. Ordered on the ovine genome v2 map, $P < 0.0001$ (solid red line), $P < 0.001$ (red dash line) 252
- Figure 8.5:** Manhattan plot of $-\log_{10}(P)$ values of SNPs for dag score at 8 months. Ordered on the ovine genome v2 map, $P < 0.0001$ (solid red line), $P < 0.001$ (red dash line) 252
- Figure 8.6:** Comparison of GWAS and GS $-\log_{10}(P)$ values for weaning weight (A), weaning weight maternal (B), live weight at 8 months (C), fleece weight at 12 months (D), dag score at 3 (E) and 8 (F) months. The 0-1 line also plotted (red line) 253
- Figure 8.7:** Comparison of dag score at 3 and 8 months (DAG3, DAG8) $-\log_{10}(P)$ values from GS analysis. The 0-1 line also plotted (red line) 254
- Figure 8.8:** QQ plot for weaning weight (A), fleece weight at 12 months (B), dag score at 3 months (C) and 8 months (D) $-\log_{10}(P)$ values. The 0-1 line is in black and the slope in red 255
- Figure 8.9:** Comparison of the observed breed combined-accuracies (r_C) versus the theoretical accuracy using Goddard's equation for each trait, and for the breeds Romney (green), Coopworth (blue) and Perendale (purple). The line of equality is in grey 261

List of abbreviations

AFEC	adult faecal egg count
AFW	adult fleece weight
BBREECH	breech bareness
BULK	wool bulk
BV	breeding value
chr	chromosome
CURV	curvature
CW	carcass weight
DAG3	dag score at 3 months of age
DAG8	dag score at 8 months of age
dNTP	deoxynucleoside triphosphate
EWT	adult ewe live weight
FDCV	coefficient of variation of mean fibre diameter
FDS D	standard deviation of mean fibre diameter
FE	facial eczema
FEC1	faecal egg count in summer
FEC2	faecal egg count in autumn
FW12	fleece weight at 12 months
GBLUP	genomic best linear unbiased prediction
GBV	genomic breeding value
GC	genotype call score
GWAS	genome-wide association study
GS	genomic selection
HapMap	haplotype map
ISGC	International Sheep Genomic Consortium
IWTO	International Wool Textile Organisation
LENGTH	wool length

Genetics of flystrike and dagginess in New Zealand dual-purpose sheep

LFW	lamb fleece weight
LW6	live weight at 6 months
LW8	live weight at 8 months
MAF	minor allele frequency
MBV	molecular breeding value
MED%	proportion of medullated fibres
MFD	mean fibre diameter
MT-EBV	multi trait-estimated breeding value
NEM1	nematodirus egg counts in summer
NEM2	nematodirus egg counts in autumn
NLB	number of lambs born
NZWTA	New Zealand Wool Testing Authority
OFDA100	Optical Fibre Diameter Analyser 100
OMIM	Online Mendelian Inheritance in Man
PC	principal components
PETA	People for the Ethical Treatment of Animals
PEV	prediction error variance
QQ	quantile-quantile
RRS	reduced representational sequencing
SAP	shrimp alkaline phosphate
SIL	Sheep Improvement Limited
ST-EBV	single trait-estimated breeding value
SURV	lamb survival
SURVm	survival maternal
TBE	Tris base boric acid and ethylenediaminetetra-acetic acid buffer
TBV	true breeding value
WWT	weaning weight at 3 months
WWTm	maternal weaning weight
