CHAPTER 4 RESULTS FOR FETUSES

Introduction 4.1

4.1 Results in fetal rat lung 4.1
4.1.1 Normal lung in the last third of gestation 4.1
4.1.2 Fetal lung haemorrhage 4.2

4.2 Non-lung fetal haemorrhage 4.2

4.3 Effect of varying mechanical index (MI) on the incidence of fetal haemorrhage 4.3
4.3.1 Fetuses with lung haemorrhage 4.3
4.3.2 Fetuses with haemorrhage in any tissue 4.3

4.4 Effect of method of exposure on the incidence of fetal haemorrhage 4.4
CHAPTER 5

DISCUSSION

5.1  Experimental methods as a model of clinical conditions
     5.1.1  Experimental equipment
     5.1.2  Mechanical index (MI) as a threshold parameter
     5.1.3  Adjustment of the ultrasound machine for use with small laboratory animals

5.2  Damage in adult rat lungs
     5.2.1  Lung haemorrhage
            Anaesthesia and lung haemorrhage
     5.2.2  Possible sources of variations within experimental groups
            Pregnancy
            Variations in experimental procedures on experimental rats

5.3  Damage in the tissues of rat fetuses
     5.3.1  General observations
     5.3.2  Fetal lung haemorrhage
     5.3.3  Haemorrhage in fetal tissues other than lungs
     5.3.4  Effect of age on fetal haemorrhage

5.4  Possible pathophysiology of haemorrhage produced by ultrasound
     5.4.1  Cavitation hypothesis
     5.4.2  Hypothesis on the association of developing bone with fetal haemorrhage
     5.4.3  Speculations on possible pathomechanism
            Vulnerability of tissues
            Site of extravasation
            Heat
            Relative motion
            Blast injury
Rapid volume and pressure changes

REFERENCES
This work is dedicated to my mother who had struggled with heart failure and died in her fifties. This motivated me to choose medicine and medical science as my life occupation.
ABSTRACT

This study investigated morphological effects of diagnostic pulsed Doppler ultrasound on adult and fetal rat lungs from 16 to 22 days gestation. A clinical ultrasound machine with two types of focused transducers (3.5 MHz, 5MHz) was used with an adjustment for an experimental animal as small as a rat. Three levels of exposure were represented by a mechanical index (MI) of 0.5, 0.6 and 1.0. Subpleural multifocal intra-alveolar haemorrhage was found to a significant degree in exposed adult rat lung and less significantly in fetal lung. The threshold for adult lung haemorrhage was considered to be between MI 0.5 and 0.6.

Fetal lungs were microscopically investigated by sectioning through the whole fetal body, which facilitated the discovery of haemorrhage at other sites. The percentage of exposed fetuses with haemorrhage is significant.

A threshold for fetal haemorrhage could not be determined because a significant variation due to age within each exposure group affected the results. The oldest 21 and 22 day old fetuses had no lung haemorrhage or significant non-lung haemorrhage. The risk for haemorrhage at all three exposure levels is more than double that of non exposed fetuses. Fetuses with lung in the canalicular stage of development (18-19 day) showed the greatest degree of lung haemorrhage.

Following laparotomy of the dam to achieve a precise and uniform exposure, a small number of fetuses within each exposure group was exposed directly. There was no higher degree of haemorrhage in these fetuses than in others indirectly exposed through the dam’s abdominal wall.

The fetal age dependency of fetal lung haemorrhage found in this study adds complexity to the issue of adult and fetal lung sensitivity to ultrasound and to the question of the pathophysiological role of cavitation in the presence of air. In addition, our result in 21-22 day fetuses does not support the hypothesis that fetal haemorrhage is associated with developing bone.

The results in this study were achieved using conditions commonly used in echocardiography and obstetrical ultrasound examinations. Therefore, caution is suggested in the medical use of ultrasound.
Acknowledgments

In adjustment to a shift from medical human radiology to science I was very fortunate to have the expert guidance throughout the research period and writing of this thesis. I would like to express my sincere appreciation to my main supervisor Assoc. Prof. A. S. Davies and co-supervisor Prof. D. J. Mellor for this and their encouragement.

Histological methods were dominant in this research and without guidance received from Mr M. J. Birtles and Mr G. R. Hessel I would have achieved little. I am grateful to them and also to pathologist Assoc. Prof. M. R. Alley who confirmed some of the important pathological findings.

An understanding of the physics of ultrasound was a crucial part of this study and consultations with physicist Dr. G. R. G. Barnes were very much appreciated.

I am grateful to Mr R. N. Ward for his technical guidance and to Ms J. D. Neale and Mr J. E. Ormsby for their assistance during experimental procedures.

The assistance of Mrs D. A. Chesterfield and Mr J. E. Ormsby from the Small Animal Production Unit (Massey University) who kindly supplied the rats used for experiments, is acknowledged.

My apology to my sons, Neshko and Milan for enduring an ever busy, working mum and my thanks for their patience during the period of completion of my thesis.

I thank Neil for his love, moral support and helpful advice over the period of this research and the writing.
