ABSTRACT

This thesis is a part of the research components associated with the National Enzootic Bovine Leukosis (EBL) Control Scheme in New Zealand. The objectives were to investigate the risk factors and temporal pattern of Bovine Leukaemia Virus (BLV) infection in dairy cattle. A case-control study was conducted using questionnaire information collected from 719 farms throughout New Zealand in 1996 and in 1997. A longitudinal study was conducted over the same period in 4 high BLV prevalence farms around Manawatu and Wairarapa regions. The results of the studies were:

(1) The presence of BLV infection was strongly related to management practices. Two predictors, namely large herd size and the purchase of stock from external sources, were strongly associated with the presence of BLV infection within herds. The number of years since farm establishment was also a risk factor which was most likely related to purchase patterns. Newly-established herds or large herds tend to buy stock from external sources and obtaining stock off-farm is likely to introduce infection. In addition, performing pregnancy testing late in the milking season and the absence of hygiene measures when undertaken mechanical dehorning of calves were significant risks which may explain within-herd transmission. The characteristics of managers from BLV-positive herds could be described as “progressive” since they were young, better educated and made use of external advisers to assist with decision making.

(2) The presence of BLV infection can be diagnosed precisely by blood test using the ELISA technique. Vertical transmission may play an important role depending on the practice of calf rearing. New cases of BLV infection principally developed in animals within the first two years of age. Prevalence and cumulative incidence of disease are mainly influenced by the existing prevalence in the herd, rather than differences in management practices. The risk of seroconversion depends on herd management factors rather than factors relating to animals. Infected animals are likely to have higher production capacity but this may be due to the fact that these animals were retained in the herd because they were high producers. The factors that predict production capacity are BLV infection status, herd and interaction between herd and BLV status.

Acknowledgments

Firstly, I express my thanks to Prof. Roger Morris, my chief supervisor, who kindly accepted me for postgraduate study in his group at Massey University and assisted me in my search for personal funding prior to the award of an NZODA scholarship. His expertise and insight ensured that this research project was coherently designed. Secondly, I would like to thank my co-supervisor Dirk Pfeiffer. His help, understanding and encouragement were provided cheerfully - despite the fact that each 'ten minute meeting' invariably stretched to an hour or more. I have appreciated and valued the opportunity to learn from him. Thirdly, I would like to thank David Hayes, my co-supervisor, without whom this project could not have been undertaken.

As my period of postgraduate study comes to a close, I am reminded of the early days when I knew little of veterinary epidemiology, statistics and computing. These two years have made me achieve in what I have never expected and never realised in my potential.

I am very indebted to the following: Mark Stevenson, who has always offered his help with practical problems and obstacles; Kevin Simmons, Chris Rogers, Britta Offergeld and the computer support people to whom I was a constant client. I also thank to my friends Tippawon Teekayuwat, Daniel Russell, Carola Sauter Louis, Sam Beckett, Klim Hüttner and Katharina Stärk who supported and comforted me at times, and Mrs. Gay Eustace, my 'host-mother', who took care of me very well while I was with her for two years.

I would also like to thank the New Zealand Government – my sponsor through the New Zealand Official Development Assistance Programme, and colleagues at Prince of Songkhla University in Thailand for doing my work when I was away.

Finally, I want to thank to my mother who has been very patiently waiting for me and who had to live on her own without my support for the past two years.
