COMPARATIVE STUDY OF SUBCLINICAL FASCIOLIASIS

IN

SHEEP AND GOATS

A THESIS PRESENTED IN PARTIAL FULFILMENT OF THE REQUIREMENTS FOR
THE DEGREE OF MASTER OF PHILOSOPHY IN VETERINARY SCIENCE
AT MASSEY UNIVERSITY

KINFE MELAK MENGESHA

March, 1991

ABSTRACT

The literature on the identification of Fasciola spp. and their intermediate hosts, the general life cycle of Fasciola and aspects of the epidemiology, clinical signs, diagnosis and treatment of infections is reviewed.

Two experiments were carried out. The first involved 18 weeks observations on 5 adult male goats each infected with 150 metacercariae of F.hepatica and 5 uninfected controls. The second involved groups of 10 sheep and 10 goats each infected with 200 metacercariae with 5 uninfected controls of each species. In both experiments, faecal, haematological, biochemical and pathological examinations were conducted. The animals were also weighed regularly.

In the first experiment, although only 15-35 flukes were established, measurable and, in many cases, statistically significant changes in a variety of parameters were observed. A depression in packed cell volumes relative to controls of approximately 20% occurred. Though haemoglobin, mean corpuscular volume and mean corpuscular haemoglobin concentration levels remained within the normal ranges, erythrocyte levels in the infected group were significantly lower than in the controls and there was a tendency for the anaemia to become macrocytic. This suggests that goats may be particularly susceptible to the effects of blood loss associated with Fasciola infections though further work is needed to confirm this.

A marked peripheral eosinophilia and elevation in fibrinogen levels were observed in infected animals. Albumin levels decreased, globulin levels increased and the A/G ratio decreased significantly relative to the control group but all levels remained within the normal ranges.

In infected animals, gamma glutamyl transferase (GGT) and glutamyl dehydrogenase (GD) levels rose to beyond the limits of the normal ranges although aspartate aminotransferase (AST) levels, which were also significantly elevated, did not. The results indicate that serum GD and GGT are particularly sensitive indicators of damage to the liver parenchyma and bile ducts caused by F.hepatica in goats and that GD is more sensitive than AST. Serum bile acids were estimated but no significant change was detected.

The ratio between faecal egg counts and the numbers of adult flukes present at necropsy was consistently lower than described for sheep with a mean of approximately 13epg/fluke (range 9-23) at the final sampling and 18epg/fluke (range 11-29) in the previous week when the egg counts were highest. This is potentially of considerable diagnostic importance and needs further investigation.

In the second experiment, the number of flukes established was extremely low in both species (mean 0.85% & 2.95% in the sheep and goats respectively) although more goats than sheep became infected. Pre-existing liver pathology in the sheep was a further complication. Consequently, little information of value was generated by the infection of goats and no data that could be used for comparative purposes were obtained from the sheep infection.

However, combination of the data from the 13 infected goats from both experiments yielded some useful information in relation to serum enzyme levels. Correlations between the numbers of flukes recovered at necropsy and peak levels of serum enzymes and various haematological parameters in individual animals were examined though only those relating to enzyme levels were statistically significant. The correlation coefficients between peak enzyme levels and fluke numbers indicated that the relationship was strongest with GGT and weakest with AST. However, regression analysis showed that there was no predictive value in the relationship with any of the enzymes because of extremely wide confidence intervals for predicted fluke numbers.

ACKNOWLEDGEMENTS

This study involved many individuals who contributed their unreserved help towards the completion of this study.

I would like to thank, most of all, my chief supervisor, Associate Professor W.A.G. Charleston, for his enormous help and guidance, not only in the formation and completion of this work, but also in the development of my way of thinking in research. I warmly thank Dr. Charleston for his invaluable guidance and encouragement during my study, research work and preparation of this thesis, which would not have been possible without his personal help. I deeply appreciate his enormous patience and understanding during all my difficult and worrying moments.

Special thanks also go to my second supervisor Mr.W.E.Pomroy for his useful advice and guidance in the setting up of my experimental work, the purchase of experiment animals and general supervision of my research. My thanks also go to Dr. Keith Thompson for allowing me to make use of the Clinical Pathology Laboratory throughout the experimental period and for his professional suggestions and advice. I am very grateful to Associate Professor Maurice Alley for his friendly help and guidance in histopathology.

Thanks and great appreciation are due to Professor B.W. Manktelow, Head of Department of Veterinary Pathology and Public Health and until recently, Acting Dean of the Faculty of Veterinary Science who made himself available and kept his office open at all times for personal, institutional and professional help. I would also like to forward my gratitude to Professor Roger Morris, for his postgraduate seminars and courses in Veterinary Economics, Statistical Analysis and Computer Techniques; and Professor David Blackmore for his part on Epidemiology.

My warmest gratitude and thanks to Ms. Barbara Adlington and Miss Shirley Calder for their invaluable help and assistance throughout the experimental work. I thank them both for their unreserved and kind assistance in the day-to-day attendance to and weekly sampling of the experimental animals. I am also deeply indebted to Barbara and Shirley

for the transport they personally provided me with to and from the site of sample collection every week. Likewise, my thanks go to Mrs. Elizabeth Davies for providing me with all technical assistance I needed in the Clinical Pathology Laboratory, Mrs. Pam Slack and Mrs. Pat Davey for their assistance in histological tissue preparation and Faris Sharpe for his assistance in restraining the animals in the postmortem room.

Others to whom my thanks are due are Mrs. Allain Scott for her valuable advice with the final preparation of this thesis, Mr. T.G.Law for his advice with the preparation of photograph and Mr. P.Wildbore for administrative assistance. I appreciate the kindness and friendly help of Miss A.K. Soe, Mrs. Michele Cooke, German Valero and Robert Sanson. Thanks to my flatmates and friends Ian Barnes, Sally Officer, Rosemary Phillips, Steve White and Toni Rasmusen who made my stay in New Zealand a pleasant one.

Finally I would like to acknowledge with gratitude the Fourth Livestock Development Project of the Ministry of Agriculture of Ethiopia and Addis Abeba University for the funding of this postgraduate study at Massey University. I kindly thank Ministry of External Relations and Trade for providing me with a scholarship to cover the university fee for the year 1990.
