# **Lower extremity kinematic and temporal changes in adolescent baseball pitchers during a simulated game**

A thesis presented in partial fulfilment of the requirements for the degree of

Master of Health Science  
in  
Sport and Exercise

at Massey University, Wellington, New Zealand.

Stacey Mikayla Kung

2015

**Abstract**

**Aim:** To investigate whether adolescent baseball pitchers change lower extremity kinematic and temporal parameters during a simulated game, which may affect performance outcomes.

**Method:** Twelve male adolescent pitchers (14 – 16 years) threw 90 pitches (6 sets of 15 pitches) from an artificial mound towards a pitching net. Angular displacements, angular velocities and temporal parameters at the hip, knee and ankle of the trailing and leading legs were collected throughout the pitching cycle. Dependent variables were analysed from the balance position through to maximal internal rotation of the shoulder. Performance outcomes of ball velocity and pitching accuracy were also recorded. The last five pitches of the second and final sets were compared to determine whether changes in the pitching mechanics and performance outcomes had occurred by the end of the simulated game. **Results:** Pitchers assumed a less upright posture and the leading leg was not raised as high at the balance position in the final set. Throughout stride phase, pitchers decreased maximal hip extension and ankle plantarflexion displacements in the trailing leg. Additional decreases in the maximal angular velocities for hip abduction and knee extension were seen throughout the stride phase in the final set. Foot contact occurred earlier in the final set, resulting in decreased hip flexion and increased hip abduction in the leading leg. No kinematic differences were observed between sets at ball release. Ball velocity and pitching accuracy decreased in the final set.

**Conclusion:** Kinematic differences in the lower extremities suggest that lower extremity musculature may have been affected by fatigue by the end of the simulated game.

Consequently, pitchers may have produced less forward momentum during the final set of pitches, which could have contributed to the decreased ball velocity. The altered balance position seems to be the underlying factor for the subsequent changes in the lower extremity pitching mechanics. Therefore, the leading leg hip flexors and the trailing leg hip and knee extensors may require strengthening to maintain the balance position. Additional

strengthening of the ankle plantarflexors would assist the hip and knee in producing consistent propulsive forces during the stride phase throughout a game.

**Acknowledgements**

First and foremost, I would like to thank my primary supervisor, Dr Sarah Shultz, for the amazing opportunity to experience biomechanics at a world-class institution in New York City. I would also like to thank Dr Shultz for all the help and advice she provided throughout the completion of this thesis and the numerous hours she dedicated to help get this done. I would also like to thank Dr Philip Fink for his help as part of my supervisory team.

I would like to thank Dr Howard Hillstrom for allowing me to work in his laboratory at the Hospital for Special Surgery. The help and support I received from Dr Hillstrom was greatly appreciated, especially for his expertise in biomechanics and statistics to help analyse the data. I would like to thank Dr Andreas Kontaxis for the opportunity to work on this project. I appreciate all his help with the upper extremity mechanics involved with this project and for all his help during the processing and analysis of the data. I would also like to acknowledge and thank Sherry Backus, Andrew Kraszewski and Mandi Gibbons for collecting the data and helping to process and analyse the data, particularly when it came to learning how to use Cortex and Visual3D. All the volunteers at the laboratory who helped to collect and process the large volume of data must also be acknowledged. Finally, I would like to acknowledge all the participants for volunteering their time to complete this very time consuming and demanding protocol. This project could not have been completed without them.

Ethics approval was obtained through the Hospital for Special Surgery Institutional Review Board.

## List of figures

- Fig. 3.1.** Anterior and posterior view of the marker set for a right-handed pitcher (scapula, ulna, radius and hand clusters on the left arm for left-handed pitchers). Solid black circles identify rigid clusters of markers, grey circles identify single markers and white circles identify the single markers used only for calibration. .... 34
- Fig. 4.1.** Mean  $\pm$  SD leading leg angular displacements (deg) during the baseline (green line) and final (red line) sets over the duration of the pitching cycle (% pitching cycle). Balance position occurs at 0% pitching cycle and maximal shoulder internal rotation occurs at 100% pitching cycle. The vertical lines at approximately 67% pitching cycle indicate when foot contact occurred during the baseline (green line) and final (red line) sets. The vertical lines at approximately 78% pitching cycle indicate when ball release occurred for the baseline and final sets. \* indicates significant differences in the angular displacements between sets ( $p < 0.05$ ). † indicates a trend towards a significant difference between sets ( $p < 0.10$ ). .... 50
- Fig. 4.2.** Mean  $\pm$  SD trailing leg angular displacements (deg) during the baseline (green line) and final (red line) sets over the duration of the pitching cycle (% pitching cycle). Balance position occurs at 0% pitching cycle and maximal shoulder internal rotation occurs at 100% pitching cycle. The vertical lines at approximately 67% pitching cycle indicate when foot contact occurred during the baseline (green line) and final (red line) sets. The vertical lines at approximately 78% pitching cycle indicate when ball release occurred for the baseline and final sets. \* indicates significant differences between sets ( $p < 0.05$ ). † indicates a trend towards a significant difference between sets ( $p < 0.10$ ). .... 51
