ACKNOWLEDGEMENTS

I am most grateful to Ms Marion Pybus my supervisor, who gave me constant and always helpful advice and encouragement whilst I was working on this study. I am also grateful to Dr Norma Chick who made a number of important suggestions. Of many other individuals who offered advice or commented on the research, I should like to especially thank Professor Nancy Kinross, for providing initial guidance and interest that resulted in many valuable outcomes.

I should also like to thank Miss D. N. Latta, Principal Nurse and Ms J. Hedwig, Senior Supervisor Maternity Unit for their cooperation.

My sincere thanks also go to all the women who participated in this study. Without their cooperation the study would have been impossible.

In addition, my gratitude is to my friends, Patricia Hickson, Pranee Tudsri, and Prissana Puvanan for their support and encouragement, and to Pramot Prasittipayong for his kind help in typing some parts of the manuscript.
I should like to express my special thanks to Ms Marion Hilder, whose thorough reading of the penultimate draft resulted in many improvements in wording and grammar.

My deepest gratitude is to my mother and my family for their invaluable encouragement and support throughout the several years while I studied at Massey University.

Finally, I should like to thank my dear husband, Jiradej, who assisted me in the use of word processing software during my manuscript preparation and who continually provided his love and support.

Apirach Sakulneya

November 1986
Based on a purposive non-random sample of 20 primiparous and 11 multiparous women who had their delivery at a general hospital, a descriptive study was conducted to explore personal and socio-cultural factors which influence women's choice of an infant-feeding method, and those factors that influence the continuation or cessation of breast-feeding. The women from both groups were interviewed four times with a similarly structured questionnaire - 3-5 days postnatally at the hospital and three times at home until the baby was 12 weeks of age. The first interview covered a retrospective review of the decision about the method of feeding and the present experience of breast-feeding whilst the questions asked at home related to the experience of breast-feeding including reasons for change of feeding method. The last interview concerned feeding experience and the women’s perception of the major advantage and disadvantage of the feeding method that they were actually using.

The result showed that all women elected to breast-feed their babies and almost all of them made such a decision prior to pregnancy or at an early stage of pregnancy.
It was found that several aspects of personal characteristics influenced women's choice of infant-feeding. The personal value system, knowledge and experience affect women's decisions to breast-feed whilst coping ability and physical problems affect the continuation or discontinuation of breast-feeding. An analysis of the demographic background failed to indicate any influence on breast-feeding. Within the Socio-cultural context, cultural practice, advice and help at hospital, and a source of help and encouragement at home, significantly affect choice and continuation of breast-feeding. Encouragement and help with household tasks from partner and family in particular appeared to be an important influence on the continuation of breast-feeding.

Implications for nursing practice and other factors relevant to the Thai situation are derived from the results. These have been discussed and suggestion for change have been made.
