Dedication

To my father, who inspired those to work hard.

**AN EVALUATION OF ANTIOXIDANT AND HYDRATION TREATMENTS FOR
THE IMPROVEMENT OF THE STORABILITY OF SOYBEAN
[Glycine max (L.) Merr.] SEEDS.**

Author: Nit Sakunnarak, Ph.D. Thesis, 1992.

Supervisors: Dr. Peter Coolbear, Dr. David W. Fountain

ABSTRACT

Antioxidant and hydration treatments were evaluated for their potential to improve the storability of soybean cvs. Amsoy and Davis under different ageing conditions (accelerated ageing at 40°C, 36-100% RH; controlled deterioration at 40°C, 20% seed moisture; or slow ageing at 35°C, 9 or 12% seed moisture).

Despite previous reports in the literature, no protective effects of treatment were found using 1% α -tocopherol, 0.1% butylated hydroxytoluene (BHT) in acetone solution for 16 h, β -mercaptoethanol 0.52-52 ppm in aqueous solution or 0.1-1% iodine in calcium carbonate. High concentrations of BHT (2.2%) or iodine (1%) caused toxic effects to germination performance (as determined by normal germination, viability, fresh and dry weights of normal seedling axes). Acetone, used as a carrier for antioxidant treatments, was toxic to soybean seeds. Initial seed moisture contents, levels of mechanical damage, treatment duration and seed lot variation were key factors affecting susceptibility to acetone toxicity. Tetrazolium staining showed that acetone did not cause damage to a specific tissue but rather increased the area of dead tissue which had been mechanically damaged.

Hydration-dehydration pre-storage treatments of soybean also showed damaging effects. Soaking treatments caused injury to low vigour lots immediately and reduced ageing resistance in high vigour material. Moisture equilibration (ME) for 24-48 h had no effects on seed performance, but an extended moisture equilibration period up to 72 h increased rates of germination loss during subsequent ageing. However, post-storage hydration treatments showed some capacity to repair damaged seeds.

Increased conductivity of seed leachate was always significantly correlated with loss of germination performance, suggesting that membrane damage was related to seed deterioration. Changes in lipid and membranes were assessed in seeds aged at 40°C, ~100%

RH or 35°C, 9% constant seed moisture. No changes in total lipid content due to ageing or treatments suggested that changes in storage lipid were not related to germination performance. Significant losses of phospholipid (PL) from cotyledons occurred 4 days after accelerated ageing. These losses were correlated with loss of seed performance, but no changes in PL contents from axes were detected throughout the ageing period. By itself, this result suggests that cotyledon damage may be an important contributing factor to seed deterioration, but the transmission electron microscopy (TEM) study indicated that damage occurring in axes due to accelerated ageing was more severe than in cotyledons.

Acetone or water soaking pretreatments increased rates of loss of germination performance which were associated with PL losses or ultrastructural abnormalities in both axes and cotyledons. In addition, ME treatment (72 h) applied to slowly aged seeds accelerated PL loss in axes but, this was unrelated to seed performance. These data therefore indicate that PL losses *per se* are not a fundamental cause of seed deterioration and may not be the first event in membrane damage. Also germinating seeds seem to be able to repair some damage of this type. No changes in proportions of polyunsaturated fatty acids were observed in either total lipid from seed tissues or microsome fractions, indicating that lipid peroxidation was not involved in seed deterioration due to ageing or treatments. This, of course, explains the ineffectiveness of the antioxidant treatments in this study and suggests that hydrolytic damage may be involved in PL loss and seed deterioration.

Possible reasons for the differences between these results and the small amount of other work published on seed treatments in soybean are discussed, but it was clear that chemical or hydration treatments of soybean are unlikely to be a commercially viable option for maintenance of soybean quality where poor storage conditions are inevitable. Nevertheless, this study indicates some interesting areas for future research into the critical events involved in soybean deterioration.

ACKNOWLEDGEMENTS

I gratefully acknowledge my chief supervisor, Dr *Peter Coolbear*, for his excellent supervision, understanding, warm encouragement throughout my study, especially for his enthusiasm to help, constructive criticism, endless patience in discussion and correction of my English. Without him, this work would not have been possible. I owe a great debt to him.

I also wish to express my sincere thanks to Dr *David W Fountain*, my co-supervisor, for his friendship, encouragement, valuable suggestions, guidance concerning lipid and membrane study and reading my manuscripts.

My gratitude and appreciation are also extended to:

Mr *Doug Hopcroft* of EM laboratory DSIR, for his excellent work in preparing samples for EM study and Mr *Raymond Bennette* for help. Mr *Craig McGill* and Mr *Richard G Burr* for their technical assistance, friendship and encouragement.

Prof *Murray J Hill*, director of the Seed Technology Centre, and Dr *John G Hampton* for their readiness to help, cheerful support, suggestions in conducting experiments, and other present and past staff of Seed Technology Centre and Botany and Zoology Department for their help in many ways, especially Mrs *Dulcie Humphrey* for her friendly encouragement and moral support particularly during my stress period.

Mrs *K Hamilton* for typing tables and references, Mr *G Donaldson* for the illustrations, and Mr *T Watts* and staff of central photographic unit for photographic work.

Mrs *Daphne Meech*, *Michael* and *Nittayaporn Hare*, Dr *Clive Cornford*, Dr *Wanchai and Siree*, *Phuengporn*, *Pontip* and *Apichai* for their help, friendship and constant moral support.

Finally, *the New Zealand Government* for financial assistance, and *the Thai Government* for granting study leave.

Appendix 3.3	Procedures for the preparation of seed tissue or membrane fraction for transmission electron microscopy. 224
Appendix 4.1	The effects of chemical treatments and subsequent controlled deterioration (40°C, 20% SMC) on dry weights of normal soybean seedlings (mg. axis ⁻¹) 8 d after sowing of lot A-1, cv. Amsoy. 226
Appendix 4.2	Effects of chemical treatments and durations of accelerated ageing (40°C, ~100% RH) on time to 50% germination (T ₅₀) of soybean seed lot A-1, cv. Amsoy. 227
Appendix 4.3	The effects of chemical treatments and subsequent accelerated ageing (40°C, ~100% RH) on axis dry weights of normal seedlings of soybean seed lot A-1, cv. Amsoy 8 d after sowing. 228
Appendix 4.4	The effects of chemical treatments, soaking seeds at different initial moisture contents and subsequent accelerated ageing (40°C, ~100% RH) on normal germination and viability of soybean seeds, cv. Davis. 229
Appendix 4.5	The effects of chemical treatments, soaking at 6% SMC prior to subsequent slow ageing (35°C, 12% SMC) on dry weights of normal seedlings (mg. axis ⁻¹) of soybean, cv. Davis, after 8 d from sowing. 230
Appendix 4.6	The effects of different durations of soaking in acetone prior to subsequent controlled deterioration (40°C, 20% SMC) on dry weights of normal seedlings (mg. axis ⁻¹) of soybean lot A-2, cv. Amsoy, after 8 d from sowing. 230
Appendix 4.7	The effect of initial seed moisture contents on viability of untreated and acetone soaked soybean seed lot A-8, cv. Amsoy, after 3 d controlled deterioration (40°C, 20% SMC). 231
Appendix 4.8	The effects of different concentrations of β-mercaptoethanol treatments and subsequent controlled deterioration (40°C, 20% SMC) on normal germination of soybean seed lot A-0, cv. Amsoy. 232
Appendix 4.9	The effects of subsequent accelerated ageing (40°C, ~100% RH) (averaged over treatments) or iodine treatment for 24 h (different concentrations averaged over duration of AA) on axis fresh weights of normal soybean seedlings of lot A-3, cv. Amsoy. 233

Appendix 4.10	The effects of chemical treatments on seed moisture contents (% FWT) of unaged seeds of soybean cv. Amsoy lot A-1 (Expt II) or Davis (Expts III and IV) after seeds were soaked at different initial moisture contents.	234
Appendix 5.1	Seedling dry weights of different seed lots of cvs. Amsoy and Davis as a result of hydration treatments and subsequent accelerated ageing (40°C, ~100% RH).	235
Appendix 5.2	The effects of accelerated ageing (40°C, ~100% RH) alone or followed by 72 h moisture equilibration (ME) with or without drying (D) on normal germination of soybean seeds, cv. Davis.	236
Appendix 5.3	The effects of slow ageing (35°C, 9% SMC) alone or followed by 72 h subsequent moisture equilibration on fresh and dry weights of normal soybean seedlings, cv. Davis, grown in soil after 17 d 50% establishment.	237
Appendix 5.4	The effects of 72 h moisture equilibration (ME) with and without drying on conductivity of leachate of accelerated (40°C, ~100% RH) or slowly aged (35°C, 9% SMC) seeds.	238
Appendix 6.1	Dry weights of seedling axes of soybean seeds, cv. Davis, affected by slow ageing (35°C, 9% SMC) alone or with 72 h subsequent moisture equilibration.	239
Appendix 6.2	Conductivity of leachate from soybean seeds, cv. Davis, affected by accelerated ageing (40°C, ~100% RH) and interactions with preliminary acetone or water soaking.	240
Appendix 6.3	Conductivity of leachate from soybean seeds, cv. Davis, affected by slow ageing (35°C, 9% SMC) alone or with subsequent moisture equilibration.	241
Appendix 6.4	The correlation coefficients (r) between germinability or viability and conductivity during AA and slow ageing.	242
Appendix 6.5	The correlation coefficients (r) between phospholipid content and seed performance during accelerated ageing (40°C, ~100% RH).	243

ABBREVIATIONS

AA	= Accelerated ageing
AOSA	= Association of Official Seed Analysts
BHA	= Butylated hydroxyanisole
BHT	= Butylated hydroxytoluene
CD	= Controlled deterioration
d	= day
ER	= Endoplasmic reticulum
GL	= Glycolipid
GLC	= Gas liquid chromatography
h	= hour
ISTA	= International Seed Testing Association
kD	= kilo-Dalton
ME	= Moisture equilibration
μ S	= micro-Siemens
month	= month
NL	= Neutral lipid
PA	= Phosphatidic acid
PC	= Phosphatidyl choline
PE	= Phosphatidyl ethanolamine
PEG	= Polyethylene glycol
PG	= Phosphatidyl glycerol
PL	= Phospholipid
PUFA	= Polyunsaturated fatty acid
RCR	= Respiratory control ratio
RH	= Relative humidity
RQ	= Respiratory quotient
SA	= Slow ageing
SMC	= Seed moisture content
TEM	= Transmission Electron Microscopy
TL	= Total lipid
wk	= week
WSB	= Water saturated butanol
