Methane emissions and mitigation technologies in cattle, sheep and red deer

A thesis presented in partial fulfilment of the requirements for the degree of

Doctor of Philosophy

in

Animal Science

At Massey University, Palmerston North, New Zealand

Natasha Madeleine Swainson

2011

## ABSTRACT

---

---

Enteric fermentation of ingested feed by ruminant livestock is an important source of methane (CH<sub>4</sub>), a potent greenhouse gas (GHG). Ruminant CH<sub>4</sub> emissions contribute approximately 31% of New Zealand's total GHG inventory; therefore reducing CH<sub>4</sub> emissions from ruminant livestock is a national priority.

The aims of this research were to investigate the effectiveness of potential mitigation technologies on the CH<sub>4</sub> emissions in sheep. This included the supplementation of monensin and coconut oil, individually or in combination, and the feeding of chicory as an alternative forage to perennial ryegrass-based pasture (pasture). The influence of ruminant age (grazing red deer) and ruminant species (housed cattle, sheep and red deer) on CH<sub>4</sub> yield were also explored.

This research showed that the supplementation of monensin to sheep may provide reductions in CH<sub>4</sub> yield (g CH<sub>4</sub>/kg dry matter intake, DMI) of up to 30%, but this was not consistent between experiments. Sheep fed chicory yielded less CH<sub>4</sub> (17%) compared with sheep fed pasture, which was suggested to be due to faster degradation rates of chicory, leading to the increased outflow rate of digesta from the rumen; this theory needs to be tested. Neither, the supplementation of coconut oil or the combination of mitigation technologies resulted in a significant reduction in CH<sub>4</sub> yield. Nevertheless, as the power to detect a significant difference between treatments was reduced, due to the high variability of estimated CH<sub>4</sub> production, it is recommended that the effects of combined mitigation technologies be retested.

Methane yield was influenced by deer age, but only at 4.5 months of age as CH<sub>4</sub> yields of deer aged 6.5 to 11.5 months did not differ and may be an artefact of the method used to estimate DMI. Mean differences of CH<sub>4</sub> yield (up to 32%) between ruminant species was found when animals were offered the same diet and constant feeding levels; cattle > sheep > deer. This study indicates that the use of a single ruminant species to model potential CH<sub>4</sub> mitigation technologies may not represent all target populations due to differences of age or species found in this study. Research is required to confirm if differences between ruminant species persist when animals are fed fresh forages and to determine if responses to potential mitigation technologies are similar with age or between ruminant species.

## ACKNOWLEDGEMENTS

---

---

I would like to express my gratitude and thanks to all those that have helped me, for without them this thesis would not have been possible. The process of a PhD is always so much more than just the production of a thesis; it is a journey of learning, both academically and personally, and even at times a contest of pure stubbornness.

- My supervisors Drs Simone Hoskin, Harry Clark and Ian Brookes.

- A special thanks is owed to Dr Ian Brookes and Prof. Garry Waghorn. Thank-you for your patience, advice and tolerance, I have am very grateful to both of you.

- To those that have helped me in the running of the experiments thank-you for all of your help, we survived the destruction of buildings, advancement of heavy machinery, make-shift facilities, flooding, the re-building of animal facilities and all that goes with it. Special thanks go to the Ruminant Nutrition and Greenhouse Gas Mitigation team at AgResearch, particularly German Molano, Anna Garland, Cesar Pinares-Patiño and Adrienne Smith, and the Deer Research Group at Massey University, particularly Martin Chesterfield and Geoff Purchas who were always there to give a lending hand with the deer.

- Dr Alasdair Noble and Dr Nicolas Lopez-Villalobos, whose advice with statistics was greatly appreciated. Gabrielle David and Kirsty Hammond for the tedious task of helping me to proof read.

- Personal and project financial assistance was gratefully received from the G.O. Antiss Postgraduate scholarship, Enterprise Scholarship, Elanco Animal Health (a division of Eli Lilly and Company), DEEResearch Ltd, Ministry of Agriculture and Forestry, Massey University Research Fund, Institute of Veterinary, Animal and Biomedical Sciences travel and postgraduate research fund, the Pastoral Greenhouse Gas Research Consortium (PGgRc) and AgResearch Ltd.

-Last, but not least, I would like thank Kristy Hammond and my partner Owen Mudgway for their support and for just being there.

## LIST OF FIGURES

<b>Figure 1.1:</b> Schematic diagram of the model used to calculate New Zealand’s ruminant enteric methane (CH <sub>4</sub> ) emissions. (DMI, dry matter intake; GEI, gross energy intake) (Anon, 2007).....	5
<b>Figure 1.2:</b> Microbial fermentation in the rumen. Microbes digest feed to simple monomers, which in turn are utilised by both primary and secondary fermenters. Methanogens prevent the accumulation of hydrogen (H <sub>2</sub> ) by reducing carbon dioxide (CO <sub>2</sub> ) to methane (CH <sub>4</sub> ). (NH <sub>3</sub> , ammonia) (McAllister <i>et al.</i> , 1996).....	7
<b>Figure 1.3:</b> Hexose fermentation by <i>Ruminococcus albus</i> in the absence and presence of methanogens. In mono-culture, <i>R. albus</i> degrades glucose to acetate, ethanol, hydrogen (H <sub>2</sub> ), and carbon dioxide (CO <sub>2</sub> ). Hydrogen inhibits NAD <sup>+</sup> (nicotinamide adenine dinucleotide) formation from NADH. In co-culture with methanogens, NADH is used to reduce protons to H <sub>2</sub> and the final products are acetate and methane (CH <sub>4</sub> ) (Fd = ferredoxin) (Miller, 1995). .	10
<b>Figure 1.4:</b> Estimated methane (CH <sub>4</sub> ) production, expressed as kcal/100 kcal feed, of sheep when fed diets of differing apparent digestibilities of energy and at three different levels of energy maintenance requirements (Blaxter & Clapperton, 1965). .....	18
<b>Figure 1.5:</b> Possible sites of microbial-intervention for lowering ruminant methane (Joblin, 1999).....	27
<b>Figure 1.6:</b> Summary of literature results for 33 treatment means showing the effect of fat from various sources on the percentage reductions in methane (CH <sub>4</sub> ) (g/kg dry matter intake, DMI) relative to the control diet. The solid line represents the regression accounting for the effect of study; $y = 5.562$ (s.e. = 0.590) $x$ percentage added fat; ( $r^2 = 0.67$ ; $P = 0.004$ ) (Beauchemin <i>et al.</i> , 2008).....	34
<b>Figure 3.1:</b> Live weight (kg, covariate adjusted means) of ewes pre- and post-lambing either receiving monensin (21 mg/day, monensin; n =10) or a placebo (control; n = 10). Monensin and placebo drenching commenced two days after lambing. <sup>abcd</sup> Differing letters denote a difference between each time point in the overall mean live weights ( $P < 0.05$ ). .....	87
<b>Figure 3.2:</b> Live weight (kg, covariate adjusted means) of twin lambs from birth until 36 days of age, with birth weight used as a covariate ( $P = 0.001$ ). Lambs were from ewes treated with monensin at 21 mg/day (monensin, n =20) or from ewes receiving a placebo (control, n = 12). Monensin and placebo drenching of ewes commenced two days after lambing. * Denotes a significant difference between means at the same point in time ( $P < 0.05$ ). .....	88
<b>Figure 3.3:</b> Pre- and post-lambing concentrations (m mol/L) of blood glucose in twin-bearing ewes with (monensin, n = 10) and without (control, n = 10) monensin supplementation, which commenced two days post-lambing. Lambing is denoted as day 0. Error bars represent the standard error of the mean. Differing letters denote a significant difference ( $P < 0.05$ ) between days in the average blood glucose concentrations across both treatment groups. ....	99
<b>Figure 3.4:</b> Pre- and post-lambing concentrations (m mol/L) of blood $\beta$ -hydroxybutyrate (BOH) in twin-bearing ewes, with (monensin, n = 10) and without (control, n = 10) monensin supplementation, which commenced two days post-lambing. Lambing is denoted as day 0. Error bars represent the standard error of the mean. Differing letters denote a significant difference ( $P < 0.05$ ) between days in the average blood BOH concentrations across both treatment groups. ....	100
<b>Figure 3.5:</b> Pre- and post-lambing concentrations (m mol/L) of blood non-esterified fatty acids (NEFA) in twin-bearing ewes, (monensin, n = 10) and without (control, n = 10) monensin supplementation, which commenced two days post-lambing. Lambing is denoted as day 0. Error bars represent the standard error of the mean. Differing letters denote a significant difference ( $P < 0.05$ ) between days in the average blood NEFA concentrations across both treatment groups. ....	101

**Figure 3.6:** Pre- and post-lambing concentrations (m mol/L) of blood urea in twin-bearing ewes, with (monensin, n = 10) and without (control, n = 10) monensin supplementation, which commenced two days post-lambing. Lambing is denoted as day 0. Error bars represent the standard error of the mean. .... 102

**Figure 4.1a.b:** Ratio of concentration of sulphur hexafluoride (SF<sub>6</sub>) and methane (CH<sub>4</sub>) gases in the breath samples of individual sheep within each measurement period, after correction for ambient concentrations of SF<sub>6</sub> and CH<sub>4</sub>. Each graph shows a sub-group (n = 10) of animals that is not related to treatments or diets fed..... 149

**Figure 4.1c.d:** Ratio of concentration of sulphur hexafluoride (SF<sub>6</sub>) and methane (CH<sub>4</sub>) gases in the breath samples of individual sheep within each measurement period, after correction for ambient concentrations of SF<sub>6</sub> and CH<sub>4</sub>. Each graph shows a sub-group (n = 10) of animals that is not related to treatments or diets fed. .... 150

**Figure A.1:** Decision tree for the inclusion or exclusion of data based on the concentrations of the gases sulphur hexafluoride gas (SF<sub>6</sub>) and methane gas (CH<sub>4</sub>) from the collection canisters of sheep and cattle. .... 205

**Figure A.2:** Percentile (%) plot of sulphur hexafluoride gas (SF<sub>6</sub>) (parts per trillion (ppt)) concentrations as measured directly from sheep (n (experiments) = 15, n (data points) = 3542) and cattle (n (experiments) = 17, n (data points) = 5170) when data is ranked from lowest to highest..... 207

**Figure A.3:** Percentile (%) plot of methane gas (CH<sub>4</sub>) (parts per million (ppm)) concentrations as measured directly from sheep (n (experiments) = 15, n (data points) = 3542) and cattle (n (experiments) = 17, n (data points) = 5170) when data is ranked from lowest to highest..... 208

**Figure A.4:** Percentile (%) plot of the ratio of sulphur hexafluoride gas (SF<sub>6</sub>) (parts per trillion (ppt)): methane gas (CH<sub>4</sub>) (parts per million (ppm)) concentrations as measured directly from sheep (n (experiments) = 15, n (data points) = 3542) and cattle (n (experiments) = 17, n (data points) = 5170) when data is ranked from lowest to highest. .... 209

**Figure A.5:** Percentile (%) plot of the ratio of sulphur hexafluoride gas (SF<sub>6</sub>) release from the permeation tube (PR) (mg/day): SF<sub>6</sub> (parts per trillion (ppt)) as measured directly from sheep (n (experiments) = 15, n (data points) = 3542) and cattle (n (experiments) = 17, n (data points) = 5170) when data is ranked from lowest to highest..... 210

**Figure A.6:** Linear regression of release rate of sulphur hexafluoride gas (SF<sub>6</sub>) from the permeation tube and the ratio of the gases SF<sub>6</sub>: methane (CH<sub>4</sub>) for cattle (n (experiments) = 17, n (data points) = 5170). .... 211

**Figure A.7:** Linear regression of release rate of sulphur hexafluoride gas (SF<sub>6</sub>) from the permeation tube and the ratio of the gases for sheep n (experiments) = 15, n (data points) = 3542). .... 212
