Niall Morrison

2000

Abstract

The present study explored the current competency status of residential mental health support workers ($n=121$). Competency was assessed through the domains of skills, attitudes and perception of the work environment. Consistent with a recovery model, the National Mental Health Workforce Development Coordinating Committee (1999) put forward 10 basic core competencies that they recommended that all mental health workers should be able to demonstrate in their work practice. Skills and attitudes self-report measures were developed to assess participant performance on these competencies. In addition, a standard measure (Ward Atmosphere Scale) was utilised to evaluate the perceived atmosphere of the participants' work environment. The aggregated results of this study appeared to show that participants were generally competent in a number of areas of work practice. However, deficiencies in critical areas of client support were identified on closer examination of the data. With regard to participants' reported skills, shortcomings were found in particular in the core competencies knowledge, assessment and intervention. Similar deficits were found regarding participant attitudes with shortcomings found in the core competencies knowledge, culturally appropriate practice, assessment and safe/ethical practice. While superior education and training did appear to influence performance on certain competencies, some deficiencies were nevertheless reported by the more highly educated and trained participants. In addition, participants generally characterised their work settings in a very negative manner such that it appears that many settings are not adhering to the philosophies of rehabilitation and recovery. Despite the identification of deficiencies, many participants did demonstrate a number of competencies combined with a commitment to professional growth. In fact, one of the most positive findings in this study was the importance practically all the participants placed on promotion of their own professional growth.

Acknowledgements

This research would have been impossible to undertake without the help of two special individuals. Firstly my wife Leanne who has been a source of inspiration, love and support over the past five years and who 'kept the faith'. Secondly Dr Kevin Ronan whose wisdom, insight, partnership, humour and encouragement made this study an enjoyable and worthwhile experience.

Special mention must be made of my families, the Morrisons in Ireland and the Utumapus in New Zealand whose support for my wife and myself made this in the main, a stress-free year. A specific thank you to my sister, Dr Aideen Morrison, for all her help.

The friendship of Andy, Renee, Simon and Anita who were all simultaneously carrying out study for their theses was inestimable, I believe, for all of the 'crew'. In addition, the unfailing humour and encouragement of Dr Ross Flett, to all of us, was a source of inspiration.

Lastly, special thanks to Finn, who didn't care about this study, only that she was walked, fed and fussed over, but provided the best 'time-out' from work.
