## ABSTRACT

The effects of chemical manipulation through the use of plant growth regulators on white clover (*Trifolium repens* L.) cv. Grasslands Pitau grown for seed were investigated in this study, using both sward and individual plant trials.

A white clover seed crop was established in autumn 1988, certified breeders seed of cv. Grasslands Pitau being sown at 3 kg/ha in 45 cm rows. Three plant growth regulators, chlormequat chloride (1.5 and 3.0 kg a.i./ha), paclobutrazol (0.5 and 1.0 kg a.i./ha) and triapenthenol (0.5 and 1.0 kg a.i./ha) were applied at two growth stages; during reproductive initiation (11 October) or at the appearance of the first visible bud (8 November). A further plant growth regulator, daminozide (2.0 and 4.0 kg a.i./ha) was applied only in November. Chlormequat chloride, daminozide and triapenthenol did not significantly affect node production, inflorescence production or seed yield, although thousand seed weight (TSW) was reduced. Paclobutrazol significantly reduced petiole length and increased the number of nodes/m<sup>2</sup>, but did not affect dry matter production. The October application of paclobutrazol at 1.0 kg a.i./ha significantly increased potential harvestable seed yield by 71 % through increasing the number of inflorescences produced, but the 57 % increase following the November application at the same rate did not differ significantly from the control. Actual seed yield differences (+25 and 26 %) were also not significant.

In the following season (1989/1990), three of the plant growth regulators (chlormequat chloride at 3.0 kg a.i./ha, paclobutrazol at 1.0 kg a.i./ha, triapenthenol at 1.0 kg a.i./ha) were applied using the same site as for the 1988/1989 trial (i.e. a second year crop), but avoiding plots previously sprayed with paclobutrazol to eliminate possible soil residual effects. Applications were either during early reproductive initiation (September), during peak reproductive initiation (October) or when reproductive buds/early flowers were first visible (November). Chlormequat chloride did not affect either vegetative or reproductive growth and development. Triapenthenol initially retarded growth (e.g. by reducing petiole length), but this effect was only transitory, and was no longer evident 3 weeks after application. Although triapenthenol applied in November increased inflorescence number at peak flowering, seed yield was not increased. Triapenthenol applied in October did not affect inflorescence number at peak flowering, but reduced TSW. Paclobutrazol applied in September, October and November reduced petiole length and leaf size,

but only application in November increased both node and stolon production. Application in October and November increased inflorescence numbers at peak flowering and harvest respectively, but seed yield was not increased. Data recorded from plots sprayed with paclobutrazol the previous season (1988/1989) provided no evidence of growth retardation through soil residual activity.

In an attempt to clarify the effects of paclobutrazol on white clover growth and development, individual plants grown from seeds selected at random from a lot of certified breeders seed were established as spaced plants (80 x 80 cm) in the field in spring of 1990. Paclobutrazol was applied at 1.0 kg a.i./ha on 6 November 1990 (when more than 75 % of the plants were initiating reproductive buds at their terminal buds) or 23 November 1990 (when more than 50 % of the plant population had reproductive buds visible on their stolons). Petiole length and leaf size were initially reduced, but beginning two months after application, vigorous regrowth occurred, to the extent that paclobutrazol treated plants became as tall as the control plants. However, retardation effects occurred again at harvest. Total plant dry matter and root:shoot ratios were not affected by paclobutrazol. Chlorophyll content/unit leaf area and leaf thickness increased following paclobutrazol application, but increases were not correlated. Seed yield and yield components did not differ from that of the control plants, mainly because plant to plant variation was very large, irrespective of treatment.

To attempt to reduce this source of variation, a further spaced plant trial was established in 1991/1992 using plants produced by clonal propagation from three distinct genotypes from within cv. Grasslands Pitau. Paclobutrazol was applied at the same rate and time as in the previous season, and while not affecting the number of nodes developed along stolons or inflorescence initiation at the stolon apices, it did significantly increase stolon production in all three genotypes through increasing secondary, tertiary and to a lesser extent quaternary branch numbers. However, not all these extra stolons were able to produce inflorescences, and this ability varied significantly with genotype. As a consequence, inflorescence number and potential harvestable seed yield were significantly increased only in one genotype following paclobutrazol application. However, paclobutrazol reduced seed abortion and increased seed weight in all three genotypes.

In individual plants, inflorescence growth and development from emergence to the seed ripening stage occurred more quickly in paclobutrazol treated plants than untreated plants. A simulated sward trial was used in 1990/1991 to determine whether the previous failures to significantly increase actual seed yield were because paclobutrazol treated plots had ripened earlier than control plots, and as a consequence more seed had been shed by the time of harvest. However, no significant paclobutrazol X harvest time interactions for seed yield or seed yield components were recorded. These results suggest that paclobutrazol did not affect seed maturity in a sward situation. Irrespective of treatment, greatest seed yield came from harvesting 25 days after peak flowering, but this did not differ significantly from harvesting 35 days after peak flowering. Delaying harvest to 40 and 45 days after peak flowering significantly reduced seed yield. As in previous sward trials, paclobutrazol application significantly increased inflorescence numbers, but large (+56 %) differences in potential harvestable and actual seed yield were statistically not significant. In each case, high data variation (CV > 30 %) was recorded. Factors responsible for the failure of apparent biological increases to be statistically real are briefly discussed.

## **ACKNOWLEDGEMENTS**

### **Bismillahirrahmaanirrahiim**

#### **In the name of Allah the most gracious and merciful**

I wish to express my sincere gratitude to Dr John G. Hampton, my chief supervisor and also to Professor Murray J. Hill, my second supervisor, particularly for their valuable guidance in the planning and writing of this thesis, constructive criticism, helpfulness in many ways and most importantly, encouragement throughout my four years of study at the Seed Technology Centre.

My sincere thanks are also extended to:

Professor Roderick G. Thomas for his advice during the conduct of my experiments, for his patience during the long and in depth discussions in the preparation of my manuscript, and especially the time he took to read and correct my manuscript.

Dr Ian Gordon for his valuable advice in the use of statistical analysis in this study.

Drs Michael Hare and John Caradus of AgResearch, Grasslands for supplying seed and plant materials used in this study.

Mr. Allan Hardacre of Crop and Food Research for his advice in the chlorophyll content experiment.

Mr Robert Southward and Mr Daniel Hampton for their technical help during the field trials.

Mrs Karen Hill for her advice in conducting seed germination testing and especially, during my final preparation for thesis binding.

All other staff of the Seed Technology Centre: Dr Peter Coolbear, Mr Craig McGill, Mrs Dulcie Humphrey and Mrs Colette Gwynne for provision of facilities and assistance in so many ways.

My Indonesian friends, especially Supanjani, Kusmintarjo, Mohammad Chozin and Hari Eko Irianto for their help in the field work.

All postgraduate students in the Seed Technology Centre for their friendship and for making my stay in New Zealand pleasant.

The New Zealand Ministry of External Relation and Trade for financing my study and living in New Zealand.

Massey University for awarding me the Helen E. Akers Scholarship.

The Ministry of Agriculture of the Republic of Indonesia for giving me an opportunity to study in New Zealand.

Finally, I would like to express my gratitude to my parents for their love, understanding and encouragement, and to Eileen Shee-Mei for her support, understanding, help and more importantly, for being by my side. To them, I dedicate this thesis.

5A.1	Tagged inflorescences at anthesis.....111
5A.2	Leaf colour change following paclobutrazol application (Photographed three weeks after application) .....114
5A.3	Structure of developed main stolons for both control and paclobutrazol treated main stolons (Photographed at harvest).....118
5B.1	The angle between the peduncle and the ground surface .....132
5B.2	Effect of paclobutrazol on the height of genotype I (Photographed on 9 December 1991).....134
5B.3	Effect of paclobutrazol on the height of genotype II (Photographed on 9 December 1991).....135

5B.4	Effect of paclobutrazol on the height of genotype III (Photographed on 9 December 1991).....	136
5B.5	Inflorescence production capacity for three genotypes (Photographed on 17 January 1992).....	163
5B.6	Seeds/floret from florets at the top, middle and bottom position on the inflorescences. X-rayed from two randomly selected genotype II inflorescences (separated by the middle line).....	177

## LIST OF APPENDICES

APPENDIX	Page
3.1A	Soil analysis of the Frewin's block.....267
3.1B	Tokomaru Soil Series .....268
3.2	The characteristics of white clover cv. Grasslands Pitau .....270
3.3	Sixty year averages for temperature (minimum and maximum), sunshine hours and rainfall at Palmerston North, and deviations from these averages during 1988/1989 and 1989/1990).....271
3.4	Effect of plant growth regulators on the germination of 1988/1989 harvested seed following scarification .....272
4.1	Effect of plant growth regulators on dry matter distribution ( $\text{g/m}^2$ ) for a second year crop of white clover cv. Grasslands Pitau at reproductive initiation (October), reproductive buds visible/early flowering (November), peak flowering (December) and harvest (January).....273
4.2	Effect of plant growth regulators on the germination of 1989/1990 harvested seed following scarification .....274
5A.1	Soil fertility analysis of the nursery block (the 1990/1991 trial).....275
5A.2	Sixty year averages for temperature (minimum and maximum), sunshine hours and rainfall at Palmerston North, and deviations from these averages during 1990/1991 and 1991/1992 .....276
5B.1	Soil fertility analysis for the 1991/1992 trial.....277
5B.2	Effect of paclobutrazol on stolon length for quaternary and quinary branches in two different genotypes.....278
5B.3	Effect of paclobutrazol on % light penetration at peak flowering for three different genotypes during full sun .....279
5B.4	Effect of paclobutrazol on % light penetration at peak flowering for three different genotypes during overcast .....280
5B.5	Effect of paclobutrazol on the number of nodes formed along quaternary branches in two different genotypes.....281
5B.6	Effect of paclobutrazol on the number of nodes formed along quinary branches in two different genotypes.....282

5B.7	Effect of paclobutrazol on the number of quinary branches/ quaternary branch for two different genotypes.....	283
6.1	Inflorescence numbers/m <sup>2</sup> on 3, 8, 14 and 19 January 1991 for the control plants.....	284
6.2	Analysis of variance for actual seed yield data from three harvests (25, 30 and 35 days after peak flowering).....	285
6.3	Analysis of variance for actual seed yield data from two harvests (40 and 45 days after peak flowering).....	285
6.4	Analysis of variance for the number of ripe inflorescences/m <sup>2</sup> from three harvests (25, 30 and 35 days after peak flowering).....	286
6.5	Analysis of variance for the number of ripe inflorescences/m <sup>2</sup> from two harvests (40 and 45 days after peak flowering).....	286
