2007**

Abstract

Compounds derived from the breakdown of glyceride esters of milk fat, such as free fatty acids and short chain esters, are recognised as playing an important role in the flavour of a range of fermented foods. Esterases, capable of hydrolysing ester bonds, and in some cases, synthesising them *via* an acyltransferase mechanism, typically enter the fermentation from the starter and adjunct lactic acid bacteria that are used to inoculate milk to initiate the fermentation process. With such an important role in the development of both desirable and undesirable flavours, understanding how these enzymes operate is essential for product control. In this study, the crystal structures of three lactic acid bacterial esterases were solved: EstA from *Lactococcus lactis*, and AA7 from *Lactobacillus rhamnosus* which are both capable of hydrolysis of short chain triglycerides as well as synthesising esters *via* a transferase mechanism, and AZ4, an esterase from *L. rhamnosus* which appears to be limited to hydrolysis reactions. Whilst all three were found to be members of the $\alpha\beta$ hydrolase family, unique features were found for each enzyme, reflecting the large differences in their primary sequences, substrate specificities and activities.

EstA and AA7 were both found to have a shallow substrate binding cleft, bisected by the catalytic machinery. The divided binding cleft suggests that during a transferase reaction the transferred group binds in one pocket, with the donor and acceptor groups (dependant on the stage of catalysis) binding in the other.

In contrast, AZ4 was found to have a single deep substrate binding cavity, extending into the enzyme interior, with the catalytic residues located near its entrance. The absence of a second binding site for an acceptor is consistent with AZ4 having only one function – that of a hydrolase.

The structures presented in this study are the first three dimensional structures of esterases from lactic acid bacteria to be reported. Their analyses, both in native form, and complexed with a variety of ligands mimicking various stages of the reaction cycle have highlighted how this basic fold can be adapted to efficiently catalyse different reactions. More importantly, in the case of AZ4, these structures have suggested that there is a novel mechanism used by the esterases to promote the enzyme reaction to proceed to completion, by preventing a futile catalytic reaction.

Enzymes are things invented by biologists that explain things which otherwise require harder thinking.

Jerome Lettvin

Acknowledgements

Many people have supported me during my time working on this project. In no particular order, I would like to thank the following people for their support and assistance:

All the members of the X-Lab past and present, especially Celia, Jana, Judith, Fiona, Kun, Stuart, Reuben, Santanu, Rose and Kirsty, and the guys next door, Andrew, Alice, Carlene, Greg, Muthu and Anandan, for their support and cheer during the past four years. Damon who came on board this project in the closing stages and did some really good work on AA7 despite being somewhat thrown in the deep end.

Trevor Loo, biochemistry guru, for his help with machines, recipes and general good advice. The “X-ray and NMR boys” Simon, Joe and Martin, and Ursula for the constant natter in the computer lab, and many, many coffees/lunches/beers. Ann, Cynthia and Pat, the best secretaries in the world.

Rosauero Roldan and Emily Chen from Fonterra Palmerston North for assistance with instruments and methods.

Professor Ted Baker, and other members of the University of Auckland Maurice Wilkins Centre for Structural Biology, and Clyde Smith from Stanford Synchrotron Radiation Laboratory for arranging for the collection of MAD datasets.

Michael Hardman and Emily Parker for useful discussions about the ins and outs of enzyme catalysis. Mark Patchett for discussions about molecular biology and catalysis. Bryan Anderson for his work on the all the enzymes, and for his assistance with software, space groups and unit cells and for showing me the ropes when it came to model building. Geoff Jameson for discussions about crystallography and enzyme mechanism in general, and for giving me the opportunity to learn about X-ray machine maintenance (and for then trusting me to do it!). Carol Taylor, David Harding, and especially David Lun, who put in a lot of hard work to kindly provide us with the inhibitors necessary to take the AA7 work to the next level.

Marie-Laure Delabre for her work on identifying, cloning and characterising the *Lb. rhamnosus* enzymes that have been integral to this project, and for her continued interest in this project.

My co-supervisor Ross Holland, who gave me the opportunity to start esterase research as a summer student in 2000, and showed faith that we would finally get some structures by going to great lengths to find the continued funding that has allowed our collaboration to finally yield some fruit.

My supervisor Gill Norris, whom I cannot thank enough for her support and assistance throughout this project, for being approachable at all times about anything, and for providing “tough love” when it was needed during the times of low motivation.

My parents for their love and support over the years, especially my mother for not balking (at least not visibly) at the idea of her son spending 10 years at university!

Finally Susan, for her love and support, and for understanding the late nights, and grumpiness when things were not working for me.

Matthew Bennett

Serine	S	Ser
Threonine	T	Thr
Tryptophan	W	Trp
Tyrosine	Y	Tyr
Valine	V	Val

Atom Numbering

This thesis uses the atom numbering system used by the Protein Data Bank (PDB). Greek letters are used to denote each atom outwards along the side chain from the C_{α} with numbers used to differentiate between atoms where branching occurs. Examples are given below. It should be noted that in .pdb files, Roman letters are substituted for their Greek equivalents.

Nucleic Acid Abbreviations

One Letter Code	Base(s) Represented
A	Adenosine
C	Cytosine
G	Guanine
T	Thymidine
U	Uridine / Uracil
R	G or A
Y	T or C
K	G or T
M	A or C
S	G or C
W	A or T
B	G or T or C
D	G or A or T
H	A or C or T
V	G or C or A
N	Any
