Abstract

The milk production response to additional feed (i.e., supplement) is dependent on the relative feed deficit (RFD) of the cow. We hypothesized that the relative feed deficit could be defined by post-grazing residual (PGR), with a greater PGR indicating less of a relative feed deficit. We undertook a computerized literature review, utilising key words associated with grazing systems and supplementary feed. Approximately 70 published manuscripts were reviewed. Only those that satisfied predetermined inclusion criteria were retained. A meta-analysis was undertaken across all the studies using random coefficient regression fitted as a mixed-model. In total, we collated data from 26 experiments and 90 treatments, wherein pasture-level variables, supplementary feed variables, and milk production were reported. Due to a lack of reporting of standard errors, two analyses were undertaken; one where responses were weighted against the reciprocal of the standard error of the mean, and one where they were not. On average, pasture DM intake declined (-0.28 kg/kg supplement DM; $P = 0.001$) and milk, fat, and protein increased ($P < 0.001$) 0.65 kg, 20g, and 30g/kg supplement DM, respectively. For every kg DM supplement consumed, PGR height and mass increased by 1.4 mm and 42 kg DM/ha. These results were similar in the non-weighted analysis. Associated with every 10 mm increase in PGR height in the control treatment, marginal milk response declined ($P < 0.05$) by 55 ± 21.6 g. The association between PGR height and pasture DMI at zero supplementary feed intake (i.e., unsupplemented group in experiment) on the PGR and pasture DMI responses to supplementary feed, were however, inconsistent in the weighted and non-weighted analysis. These results will enable farmers to use the change in PGR when feeding supplements, to estimate likely marginal milk production response to supplementary feeds. These results are associations only and need to be tested in controlled, interventionist, experiments. Due the number of variables affecting MR, we cannot conclude that anything is causative.

Acknowledgments

Firstly I must thank DairyNZ for providing the opportunity and financial support that allowed me to undertake this project. To study in a supportive environment, surrounded by the scientists who authored many of the works that I cited in this thesis, and who were always willing to answer questions, has been invaluable.

I would like to express my sincere gratitude to my supervisor Dr. John Roche for the continuous support and patience. Each meeting left me feeling motivated. Without John as my supervisor I would never have made it to China and still managed to get this thesis to the finish line. It has been a privilege to work beside him. I could not imagine having a better advisor, mentor and friend. Thank you for your life advice, your dad jokes and for always replying to my emails at ridiculous hours of the night.

My sincere thanks also go to Barbara Dow, who taught me everything I know about statistics. Without her support, it would not be possible to conduct this research. Thank you for always having time for me, and for keeping tabs on my progress. I don't know what direction this project would have taken had you not been there to help me.

Special thanks must also go to Dr. Danny Donaghy who timelessly read and re-read my literature review, and explained the intricacies of grazing management to me. Thanks also to my family and to my friends; Holly, Louise and Charlotte, for their understanding and encouragement as they too worked on their Masterate and PhD theses.
