# Abstract

In many countries around the world Information and Communication Technologies (ICT) are being leveraged to produce efficiency gains and cost reductions in healthcare by making health information more readily available in clinical contexts. This raises issues as to the use of health information in clinical decision making at point of care, as relying on poor quality information in this context can have serious consequences. This thesis investigates quality criteria that are used when assessing health information, with the objective of formalising those criteria for use with a prototype software system. Literature, as well as standards and currently used forms of electronic health records, were reviewed for what they offer for assessment of health information quality. A lack of criteria from these sources necessitated interviewing practicing General Practitioners (GPs) to determine criteria important to them, and how they assessed the information they want to use. Interviews were of a semi-structured type using vignettes, for clinical context. Recruitment used a Snowball methodology. Results were analysed and interpreted using Thematic Analysis and showed the GPs assessed information using criteria based on tacit knowledge, formed from community knowledge and past experience.

The Quality Criteria (QC), discovered to be integral to this process, were formalised using the developed Quality Criteria Model (QCM). A prototype system was developed to demonstrate that using a current health information standard, meta-data could be used to detect the presence of QC within health information and capture these via instantiation of the QCM. The results of successful detection of QC are then Health Information Quality Indicators (HIQI). Contributions for this thesis include the following: the set of discovered QC, thematic maps that capture the combination of criteria and the process used when applying them, the formalised model for QC (the QCM), determination that additional meta-data will be required to detect those QC categorised as being subjectively evaluated, and the demonstration that a software system can detect, and capture, QC found in health information. Implications are discussed such as that just having access to information is insufficient, and subjectively evaluated QC are problematic for implementation and use. Finally, conclusions are drawn and future work suggested such as user interface development for HIQI representation, alternative search algorithms for QC detection, and further development of the prototype toward a production system.

# Acknowledgements

This thesis would not have been completed without the help of many people. I would like to take this opportunity to thank those who helped with this project.

Deep appreciation goes to my three supervisors: Prof. Hans W. Guesgen, Dr. Inga Hunter and Dr. Kudakwashe Dube. Many thanks for the guidance and expertise shown throughout. The complimentary skills that each brought to the project helped in immeasurable ways, along with the encouragement and patience. It was not only the help with the research that was appreciated, but also the support shown on a personal level.

My thanks to staff in the School of Engineering and Advanced Technology (SEAT), especially Michele Wagner, who helped in innumerable ways, and Prof. Stephen Marsland who supported the project when needed. I would also thank my fellow postgraduate students Gareth, Yuliya, Jawad and An, with who I shared an office. The help, encouragement and light relief, along with some lively discussions, provided along the way will always be remembered.

I would also like to thank Angela Baker for wise and supportive council, it really helped. Also, thanks to Janene Walter from Massey University's Graduate Research School for assistance with the process of completing a PhD.

Thanks to Massey University for financial support in the form of the Vice-Chancellor's Doctoral Scholarship, without which I would not have started this project. Also, to SEAT for part-time work opportunities and for the allocation of a budget for research expenses.

I am also grateful to those who participated in the interviews that formed part of this research. Without the interviews, this project would not have been possible.

Last, is thanks to family and friends who showed an interest and continued to ask how it was all going.
