ABSTRACT

Divergent selection was employed to establish high and low lines for liveweight-adjusted backfat depth (LABF) assessed ultrasonically in Southdown sheep. The selection lines were initially constituted from several sources with stock brought-in during the first three years of the experiment (1976-1978). These first years were used to evaluate ultrasonic equipment for measuring backfat depth. The lines were closed in 1979. Data analysed in this study were collected over 8 years (1979-1986) representing, approximately 2.66 generations.

Selection was practised in two stages, with a preliminary selection based on the first LABF on the rams and ewes, and a final selection based on an average of all measurements assessed throughout the year for the rams only.

Direct selection for high or low backfat depth resulted in the 1986 born animals in the high line having about 1.69mm (59.6%DEV) and 2.00mm (49.57%DEV) thicker backfat than the low line in the rams and the ewes, respectively. The responses to selection per unit of cumulated selection differential were in most cases high. Due to prior selection and difficulties in assessing the selection pressure, it was concluded that these regressions poorly represented the selection process.

Correlated responses to selection for and against backfat depth were generally small. However, consistent positive correlated response were observed in liveweight-adjusted height and length (LAH

and LAL) over the selection period. These responses imply a negative genetic correlation between these traits and backfat depth. This finding was in agreement with the published literature.

Phenotypic correlations were calculated within-trait between-days and between-traits within-days. Correlations were pooled within-trait following tests of homogeneity. The within trait values were generally moderate to high and they were in agreement with the values reported in the literature. The between-traits correlation values were generally low, but were consistently negative for LABF-LAH and LABF-LAL, and consistently positive for LAL-LAH. Repeatability estimates, using the within-trait combinations, were also in agreement with the literature and suggested a moderate to high repeatability for LABF and LAH. Repeatability estimates for LAL were low to moderate and they were slightly smaller than the values reported in the literature.

Estimates of the heritability of LABF varied with method used. The paternal half-sib method resulted in low values (0.14 to 0.19) while dam/offspring method gave moderate values (0.29 to 0.43). Corresponding heritability estimates for LAH and LAL were about 0.31 and -0.14, respectively. These values were smaller than other results quoted in the literature. It was concluded that truncation selection on LABF reduced the genetic variability of these traits, although not to the same extent as for LABF.

It was concluded that divergent selection for LABF was effective, resulting in lines with significantly different backfat depth at the same liveweight. Furthermore, selection for low LABF led to significantly longer and taller animals.

ACKNOWLEDGEMENTS

In the pursuit of my degree, many teachers, colleagues and friends helped me endure this rewarding experience. To all these people, my deep gratitude and sincere thanks. Space, but surely not appreciation, permits me to mention only those who were directly involved with my research.

First and foremost the supervisors of my dissertation, Dr. Hugh T. Blair and Dr. Roger W. Purchas for their guidance and advice throughout the preparation of this work. I am particularly grateful to them for encouraging me when it was mostly needed. I would also like to thank them for the unique experience I gained by working under their supervision.

Professors A. L. Rae and R. D. Anderson for their helpful comments and suggestions in quantitative genetics and biometrics. Undoubtedly, the content of my thesis has significantly improved by their insightful remarks.

I would like to thank my sponsors The Universidad Autonoma Chapingo, The Ministry of Foreign Affairs of New Zealand, The Consejo Nacional de Ciencia y Tecnologia (CONACYT) and The Asociacion Nacional de Universidades e Institutos de Enseñanza Superior (ANUIES), who provided with financial support during my studies.

Mr. J.Rendel, Mr. B.Southey, Mr. P.Walsh, Mrs. K.Hamilton and the Computer Centre Staff for your help in the biometrical analysis and reading of this manuscript.

All Post-graduate students and staff of the Department of Animal Science. Thanks to all of you for your support and friendship throughout my time at Massey University.

Finally, but the most important people in my life, to my wife Elizabeth and our son J. Vicente were long-suffering with my depressions and absence, but also who played an important role in enabling me to complete this difficult task. This acknowledgement is extended to my parents Vicente and Lucia, my brother Alberto and my sister L.Guadalupe. Wherever you are...you are in my mind.
