USE OF SEMI-ANAEMIC PIGLETS
TO MEASURE IRON BIOAVAILABILITY
OF MEAT AND MEAT FRACTIONS

A thesis presented in partial fulfilment of the requirements
for the degree of

Master of Science
in
Nutritional Science

at Massey University
Albany - Palmerston North
New Zealand

WISNUDY WIDJAJA

2003
APPLICATION FOR APPROVAL OF REQUEST TO EMBARGO A THESIS
(Pursuant to AC 98/168 (Revised 2), Approved by Academic Board 16.02.99)

Name of Candidate: WISNUDY WIDJAJA_________ ID Number: 00301493___________

Degree: MSc________________________ Dept/Institute/School: IFNNH___________

Thesis Title: USING OF SEMI-ANAEMIC PIGLETS TO MEASURE IRON BIOAVAILIBILITY OF MEAT AND MEAT FRACTIONS

Name of Chief Supervisor: Patrick C.H. Morei _______________ Telephone Extn: 5238

As author of the above named thesis, I request that my thesis be embargoed from public access until (date) October 2005 for the following reasons:

☐ Thesis contains commercially sensitive information.
☐ Thesis contains information which is personal or private and/or which was given on the basis that it not be disclosed.
☐ Immediate disclosure of thesis contents would not allow the author a reasonable opportunity to publish all or part of the thesis.
☐ Other (specify): __________________________________________________________________________

Please explain here why you think this request is justified:

The work completed in this Thesis is part of a research program funded by the Meat Biological Consortium. MBG has requested that the thesis be embargoed as it contains some commercially sensitive information.

Signed (Candidate): ___________________________ Date: 28/7/03

Endorsed (Chief Supervisor): ___________________________ Date: 28/7/03

Approved/Not Approved (Representative of VC): _______________ Date: 30/7/2003

Note: Copies of this form, once approved by the representative of the Vice-Chancellor, must be bound into every copy of the thesis.
ABSTRACT

Iron deficiency is a major nutritional problem. According to the World Health Organization (WHO), there are approximately 3.7 billion people in the world with iron deficiency (WHO, 2000). Red meat is known to enhance iron absorption due in part to the presence of a meat factor. Domestic pigs (Sus domesticus) have been utilised as models for humans in many medical and nutritional studies. The first experiment reported here used 20 4-week-old piglets to compare the bioavailability of iron in diets containing meat (ME), a water-soluble extract of meat (SA), a water-insoluble fraction of meat (SR), and a meat-free control diet (CO). Bioavailability of iron was assessed on the basis of changes in iron-related blood parameters over a 4-week feeding trial. Iron retention in haemoglobin, red blood cell counts (RBC), haemoglobin levels (HGB), haematocrit (HCT), and mean corpuscular volumes (MCV) for ME, SR, and SA was significantly higher (p < 0.05) than for CO indicating that all meat fractions enhanced the bioavailability of iron. For some blood parameters the iron status of group SA was significantly lower (p<0.05) than for groups ME or SR. It is concluded that the meat-factor is primarily present in the water-insoluble fraction of beef.

In the second experiment nine four weeks old of age female pigs were allocated into three groups of diet treatments, i.e. E200, which contained 48 g/kg live weight\(^{0.75}\) of meat extrinsically labelled with Fe\(^{57}\); I200 and I300, which contained 48 g/kg liveweight\(^{0.75}\) and 69 g/kg liveweight\(^{0.75}\) of meat intrinsically labelled with Fe\(^{57}\). The isotope labelled diets were fed only on day 0. Afterwards all pigs received the same weaner diet. The pigs were also injected by \(^{58}\)Fe via \textit{intra venous}. E200, I 200, and I 300 were not significantly different (p > 0.05) in growth parameters (i.e. average daily gain and average daily feed intake) and in the blood parameters (i.e. white blood cells and RBC, HGB, HCT, MCV, the mean corpuscular hemoglobin and the total iron body in the blood circulation) and iron absorptions. The findings indicate that the different labeling method and different meat levels gave same results.
ACKNOWLEDGMENTS

I wish to express my special gratitude to Dr Patrick C.H. Morel for his patience, guidance, motivation, and statistical analysis advice throughout the trials and writing of this thesis.

I would also like to thank Assoc. Prof. Roger W. Purchas for his contribution toward the running of trials and for offering constructive advice on improving the text.

I would also like to extend my gratitude to NZMeat for financing the trials, Dr. Scott Knowles for conducting iron isotope-related jobs, Dr. Brian Wilkinson for processing meat extractions, Ms Jo Melai for coordinating the trials, Mr Edward James and Ms Karin Weidgraaf for carrying out blood samplings.

Last but not least I would like to thank my wife Susan for her encouragement and moral support throughout the duration of this study. This thesis is dedicated to my children Jonathan and Pamela.

INTRODUCTION

Iron deficiency is one of the major nutritional problems. According to the World Health Organization (WHO), there are approximately 3.7 billion people with iron deficiency status (WHO, 2000). Iron deficiency, especially iron deficiency anaemia conditions, reduces human productivity and increases public health costs enormously.

Domestic pigs (Sus domesticus) have been utilised as a model for human in many medical and nutritional studies. It is a mammal, monogastric animal and its physiological/digestive system has many similarities to human.

Red meat is known as a good source of haem iron, which has a higher bioavailability than non-haem irons. A meat factor is involved in this enhanced effect. To find out more about the meat factor, beef meat was separated into a water-soluble fraction and a water-insoluble fraction. In the first experiment, these fractions were fed to semi-anaemic pigs and their iron status monitored.

Stable isotopes are preferred to radioisotopes in nutritional studies for ethical and health reasons. In the second experiment, lamb meat was, intrinsically and extrinsically, labelled with iron stable isotopes to study iron absorptions in semi-anaemic pigs. The aim was to determine whether the level of stable isotope in the lamb meat was high enough to detect clear changes in the level in red blood cells following consumption of the meat, before conducting a human study.
