FAECAL AND TONSILLAR CARRIAGE OF \textit{YERSINIA} SPP. BY PIGS

A DISSERTATION PRESENTED IN PARTIAL FULFILMENT (25 \%) OF THE REQUIREMENTS FOR THE DEGREE OF MASTER OF VETERINARY STUDIES IN VETERINARY PUBLIC HEALTH AT MASSEY UNIVERSITY

ALICE ALMA C. BUNGAY
MAY, 1997
ABSTRACT

Pigs are considered important reservoirs for pathogenic Yersinia spp. which cause disease in humans. Results of many surveys have demonstrated the common occurrence of Y. enterocolitica and related species in the tonsils and intestinal tract of healthy slaughter-age pigs. However, the source of infection remains unclear. There is a dearth of information as to when pigs become infected hence, there is a need to conduct further studies not only among slaughter pigs but also among pigs belonging to different age groups on the farm. This study was conducted to determine the faecal and tonsillar carriage of different Yersinia spp. by pigs belonging to different age groups, characterise the species isolated by biochemical and serological methods, and determine the in vitro virulence characteristics of the isolates by simple assays.

The study was conducted in two phases: first on a known or suspect Y. enterocolitica-positive farm within Massey University and second in a slaughterhouse where pigs from the suspect farm are sent for slaughter. A total of 54 faecal samples were collected from pigs belonging to six different age groups including 3-4 days, 2 weeks, 3 weeks, 4 weeks, 8 weeks and 12 weeks together with samples from the sow and one pooled sample from the floor. All of the 54 faecal samples collected were found negative for Yersinia spp. after the 21-day cold enrichment, subsequent plating onto CIN agar and use of primary screening tests. In the second phase, a total of 50 samples representing 25 faecal and 25 palatine tonsils were collected from slaughter pigs with ages ranging from 20-24 weeks. Out of the 25 faecal samples, there were two isolates of Yersinia frederiksenii and one isolate of the unusual or new biotype of Yersinia enterocolitica. Of the 25 samples of palatine tonsils collected, three of the isolates were unusual strains of Y. enterocolitica and two were Y. pseudotuberculosis Group I or serotype I. All isolates were confirmed by biochemical tests. The two isolates of Y. pseudotuberculosis were confirmed as Group I by serological tests. In this study, sample collections were done in the months of August and October when Group I was isolated conforming to the results of De Allie (1994) when serotype I was found only in winter and spring.

The pathogenic potential of the eight isolates of Yersinia spp. were tested for in vitro virulence associated characteristics using the four simple tests namely salicin fermentation/aesculin hydrolysis, D-xylose fermentation, pyrazinamidase (PYZ) test and Congo Red-magnesium oxalate (CR-MOX). In this study, the unusual strains of Y. enterocolitica isolated from the
tonsils and faeces were salicin-aesculin positive, xylose-positive, CR-MOX negative and PYZ negative. Except for PYZ, all three tests suggest the non-pathogenic potential of this unusual strain of \textit{Y. enterocolitica}. The pathogenic potential of \textit{Y. pseudotuberculosis} Group I isolated from the pig tonsils was shown by CR-MOX and PYZ tests. Both isolates were CR-MOX positive and PYZ negative. \textit{Y. pseudotuberculosis} is considered a potential pathogen as shown by \textit{in vitro} virulence tests and should not be overlooked as a causative of human disease.

It was shown in this study that not all pigs are infected with pathogenic and non-pathogenic species of \textit{Yersinia} even if they have been established to harbour the organisms either in their tonsils or faeces. However, pigs sent for slaughter may carry \textit{Yersinia} spp. in their tonsils or faeces suggesting the role of other factors such as management and husbandry practices or contact with other animals during lairage, or from possible cross-contamination during processing at the slaughterhouse. Slaughter pigs are important source of \textit{Y. enterocolitica} infections in humans, hence it is important to prevent or reduce the risk of possible contamination in the slaughterhouse by these organisms. Further investigations are needed to determine the pathogenic potential of the unusual strains of \textit{Y. enterocolitica} and its possible role as a causative agent in human disease. Since \textit{Yersinia} spp. were not recovered from faecal samples of pigs in the farm belonging to different age groups in this study, there is a need to conduct further studies using tonsillar samples or swabs instead of faeces. As shown in this study and other published reports, tonsils yield more isolates of \textit{Yersinia} spp. compared to faecal samples.
ACKNOWLEDGEMENTS

I would like to express my sincere gratitude and appreciation to the Ministry of Foreign Affairs and Trade (MFAT) for the New Zealand Official Development Assistance-Postgraduate Scholarships (NZODA-PGS) which enabled me to pursue a Masters degree. I also give thanks to the staff of the International Students’ Office especially to Ms. Dianne Fountaine-Cody.

I am greatly indebted to Prof. Colin R. Wilks for giving me the opportunity to study and pursue this quest for knowledge. His invaluable guidance, moral support, encouragement and supervision has contributed tremendously to my professional career and development.

I would also like to thank my supervisors, Mr. Per Madie and Dr. Jane Hunter for their outstanding roles in guiding me throughout the study period. I can’t thank them enough for their guidance, patience and encouragement in helping me with this study.

I am also very thankful to Mr. Stan Fenwick, a *Yersinia* expert for his valuable contribution, comments and suggestions.

With utmost gratitude and appreciation, I would also like to acknowledge the following:

Dr. Barb Frey for her assistance in helping me to organise the collection of samples at the study farm.

Mr. Peter Wildbore, Ms. Jan Schrama, Ms. Magda Gwodz, Ms. Kylie Walker, Ms. Pam Slack, Ms. Pat Davey and Mr. Faris Sharpe for their friendly assistance during my study.

The two other members of the “Three Musketeers”: Kyung Ho Shin and Durai Subramaniam for their help especially during sample collection.

Mr. Paul Lysagt and the staff of National Pig Breeding Center for their kind permission to collect samples from the farm.

I would also like to acknowledge the productive and enjoyable interactions I had with the staff and postgraduate students in the Department of Veterinary Pathology and Public Health and wish to extend special recognition to Assoc. Prof. Maurice R. Alley, Dr. Mark Collett, Dr. Keith Thompson, Dr. John Lumsden, Dr. Joanne Meers, Mr. Stan Fenwick, Dr. Jane Hunter, Assoc. Prof. Tony Charleston, Dr. Bill Pomroy, Mr. Neil Christensen, Prof. Colin R. Wilks and Mr. Per Madie for providing an opportunity to study Diagnostic Pathology, Public Health and Meat Hygiene. It has been a great pleasure for me to work with such people full of dedication towards achieving excellence.

Mrs. Allain Scott, Mrs. Wendy Graham and Ms. Nicola Purdue-Smith for their administrative assistance.

Special thanks is also given to Dr. Heather Simpson for being an adviser who always have a cheerful smile.
I especially wish to acknowledge my husband, Everest for his love, understanding, encouragement, patience, moral support, sense of humour and also for keeping our household in good order while I was busy working with my dissertation. Also to our two daughters, Resalice Anne and Raisa Dana Marie for their love and understanding.

I am also thankful to my foster parents here in New Zealand, Papa Ian and Mama Ruth Mills, and also to our friends, Vince and Heather Norrish for making New Zealand our home away from home.

To my parents, brothers, sisters, in-laws and friends in the Philippines for all the moral support, confidence and believing in my capabilities to pursue this graduate study.

Lastly, I am offering my work to the Lord God Almighty for making all things possible.
